16. Abstract <p>A program has been carried out to make modifications to the Lockheed-Huntsville Mobile Laser Doppler Velocimeter (LDV) system; to calibrate and operate the system at the John F. Kennedy (JFK) Airport; to obtain a data base of wind, wind shear, and wake vortex measurements; and to assess the basic operational capabilities of the system based on these measurements. The basic operational capabilities, resolution, and integrity of a scanning LDV for the remote sensing of winds, wind shear, and wake vortices at terminal areas have been established.</p> <p>Volume I, 150 pages, contains text.</p>

Appendix A  
DATA REPORT

This appendix summarizes the wake vortex and wind measurements made with the Lockheed-Huntsville LDV during the research program. The logs for the LDV measurements showing the run identification, time of day, estimated wind, and operator comments are presented on pages A-2 through A-11. The cataloged wake vortex measurements are presented on pages A-12 through A-253 in terms of the trajectory of the wake vortex with respect to the runway centerline. At the start of each new tape, the input parameters selected for the VAD and Vortex Track program are given for the wake trajectory calculations.

Appendix B  
COMPUTER PROGRAM DOCUMENTATION

This appendix describes the computer programs developed and utilized during the research program. The discussion of the off-line computer software package includes flow charts of the basic routines and subroutines.

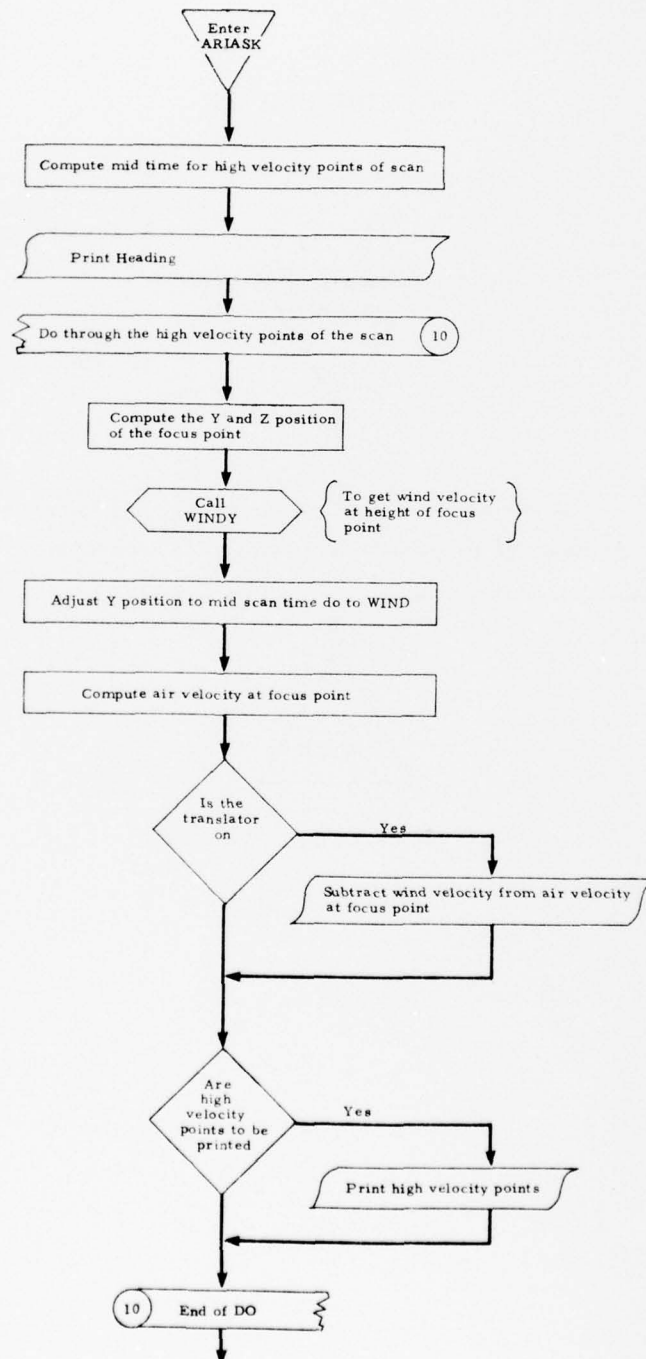

# MACRO FLOW CHART OF VAD AND VORTEX TRACK PROGRAM

# ROUTINE ARIASK

Finds position and velocity of points in each normal scan.

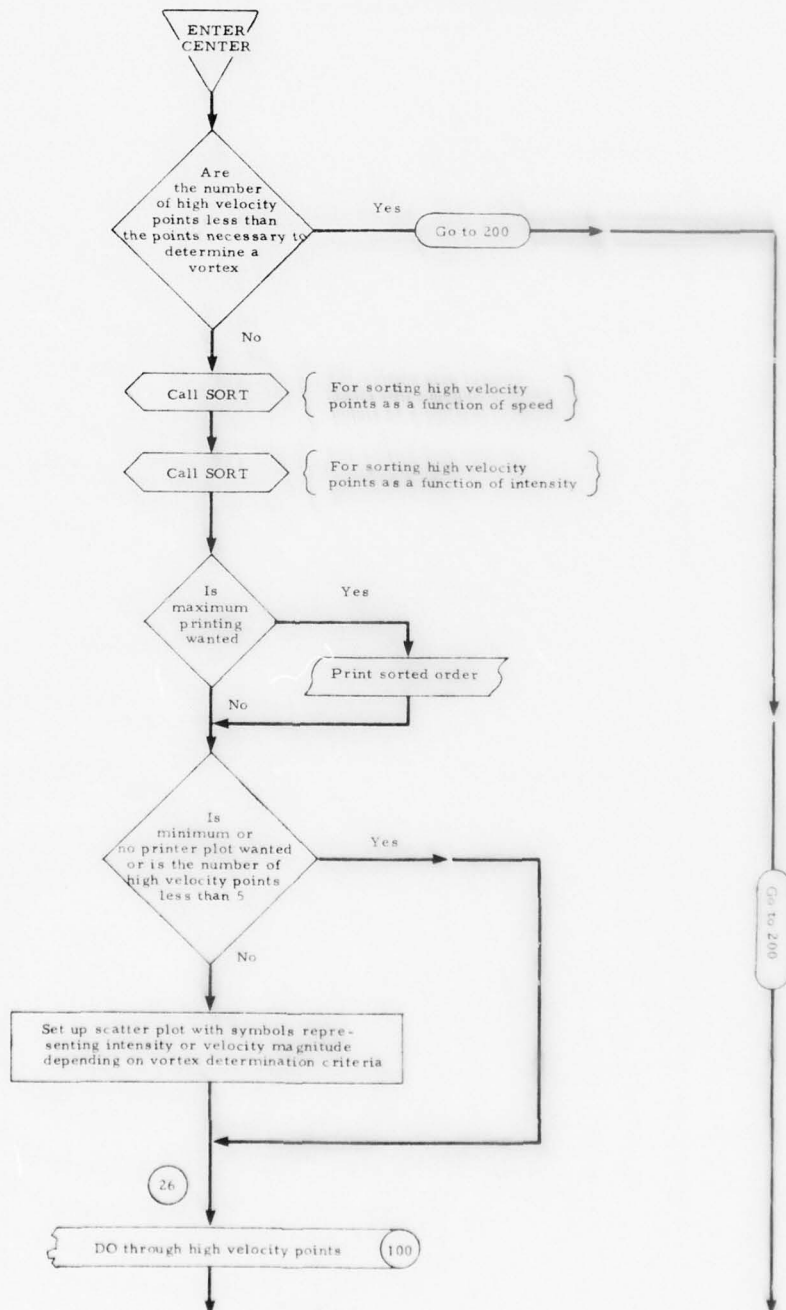

# ROUTINE BDOWN

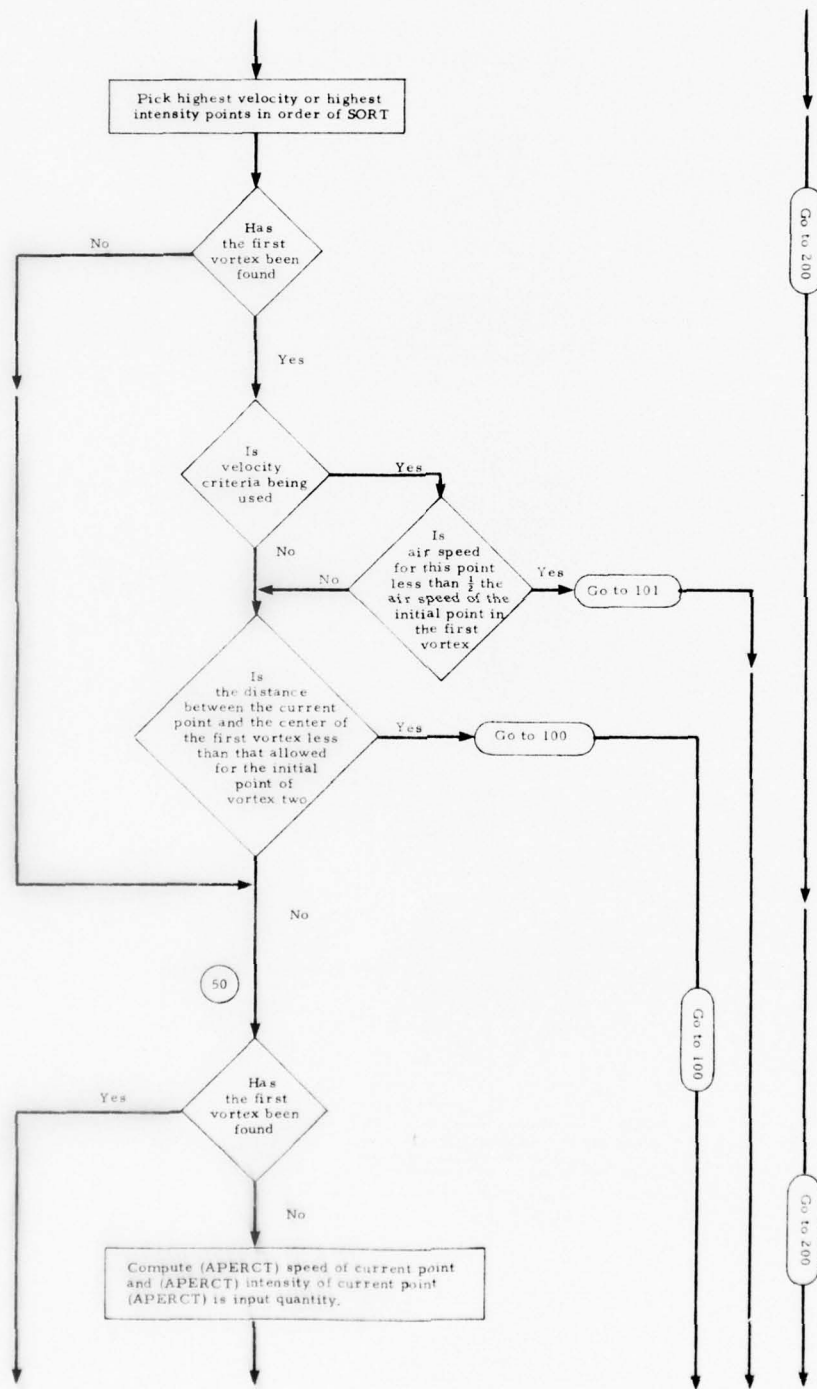

Separates 16 bit  
words written by  
SEL computer

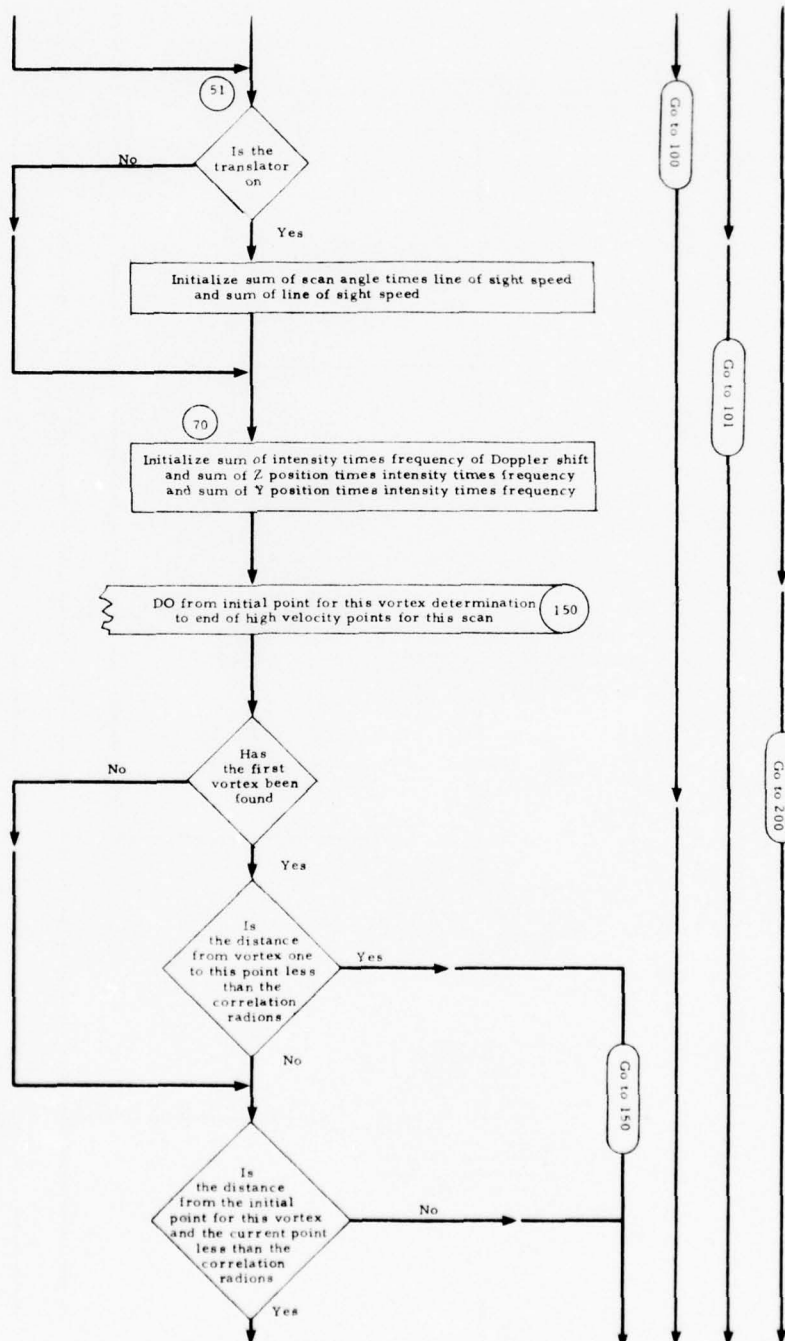

# ROUTINE CENTER

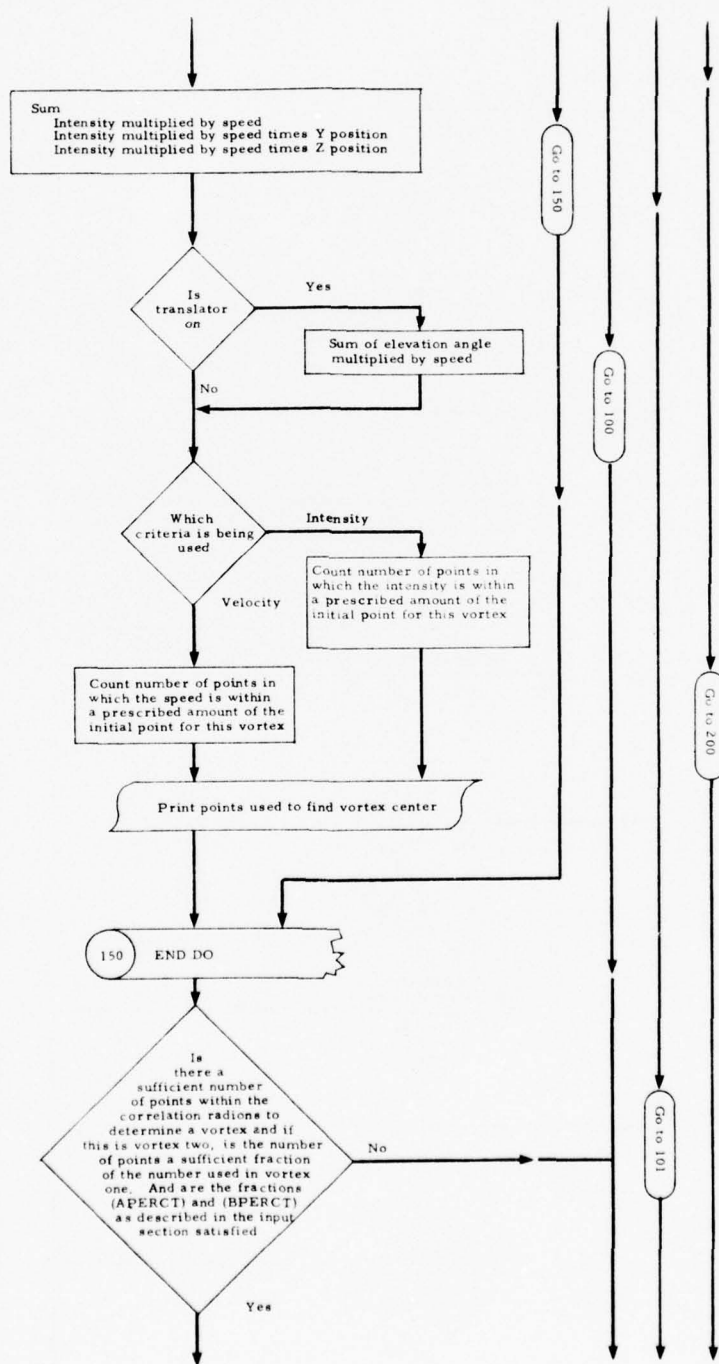

Locates vortices and  
computes circulation.

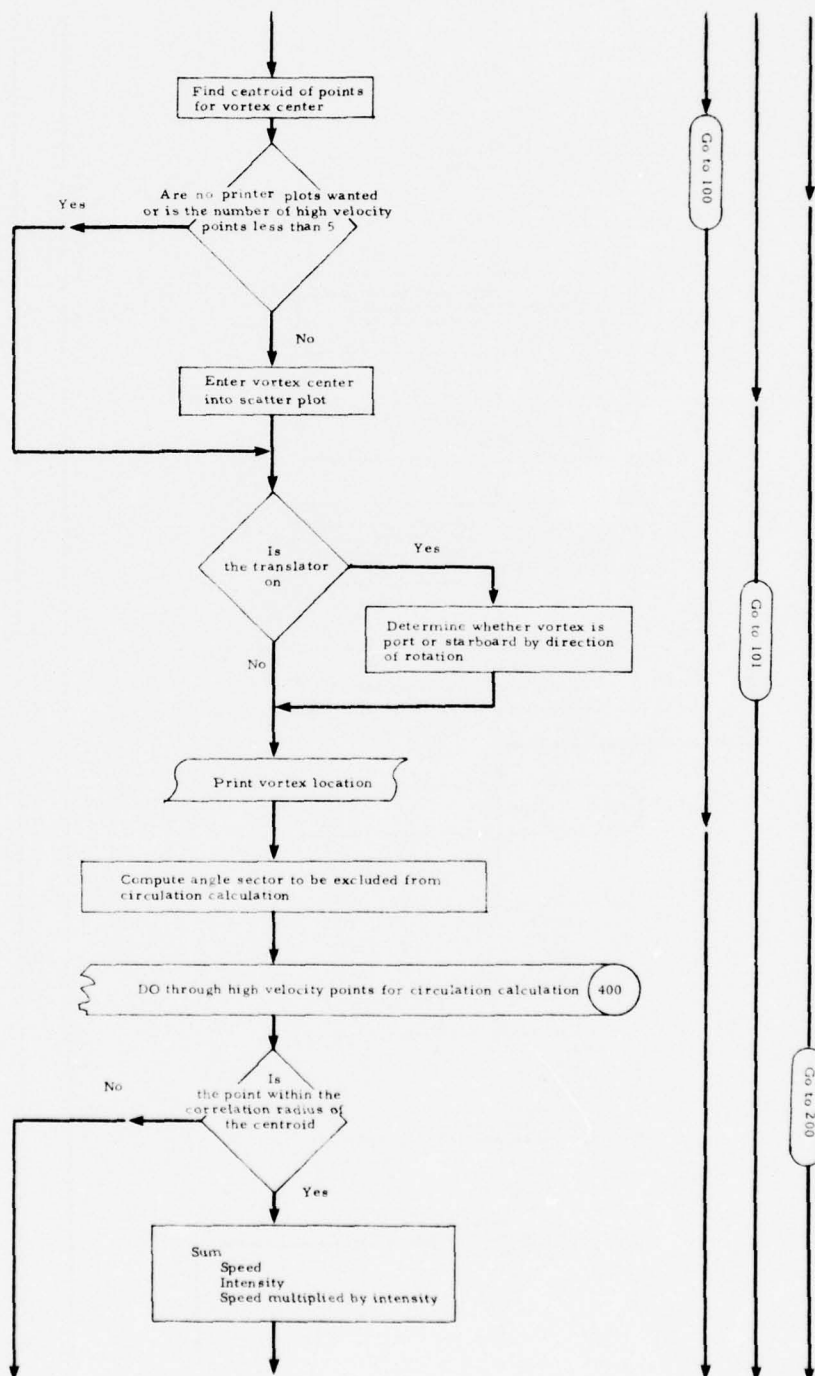

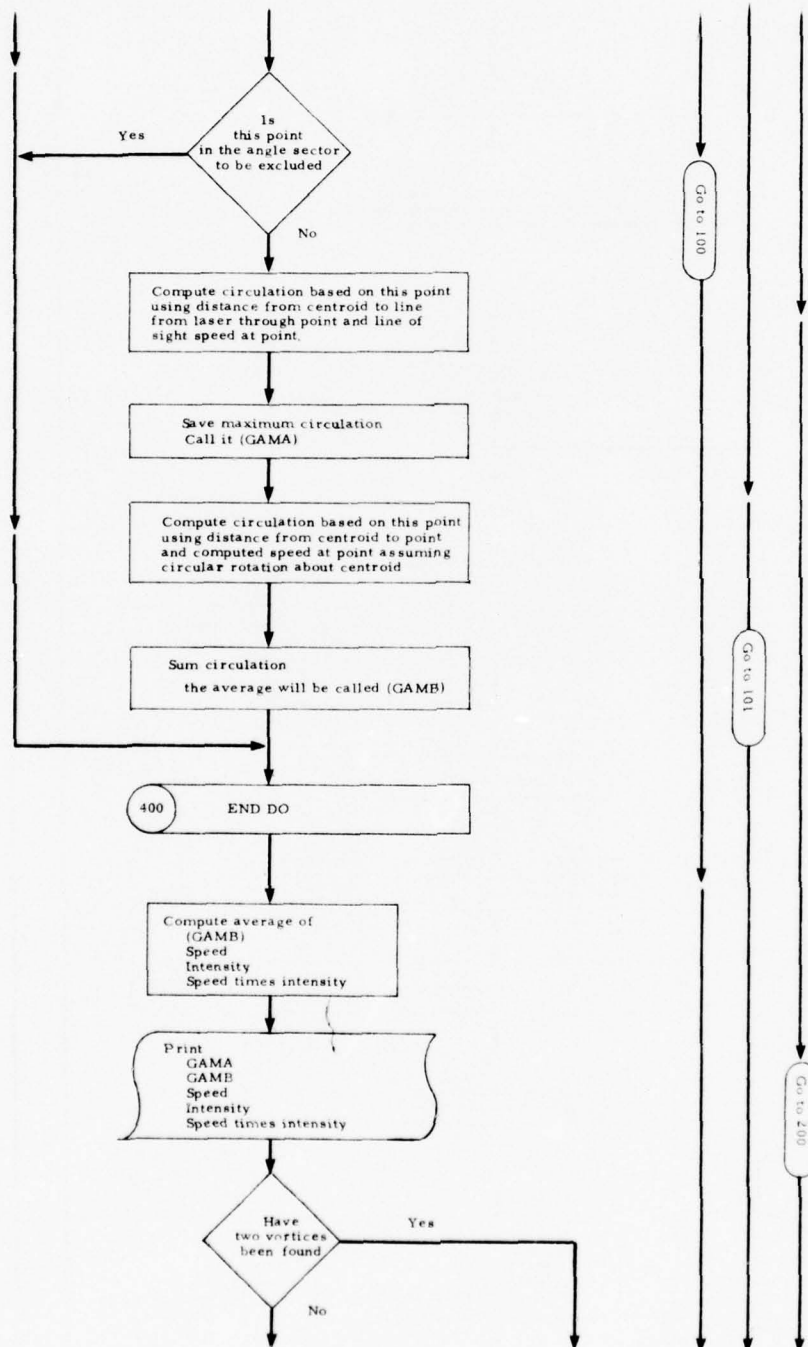

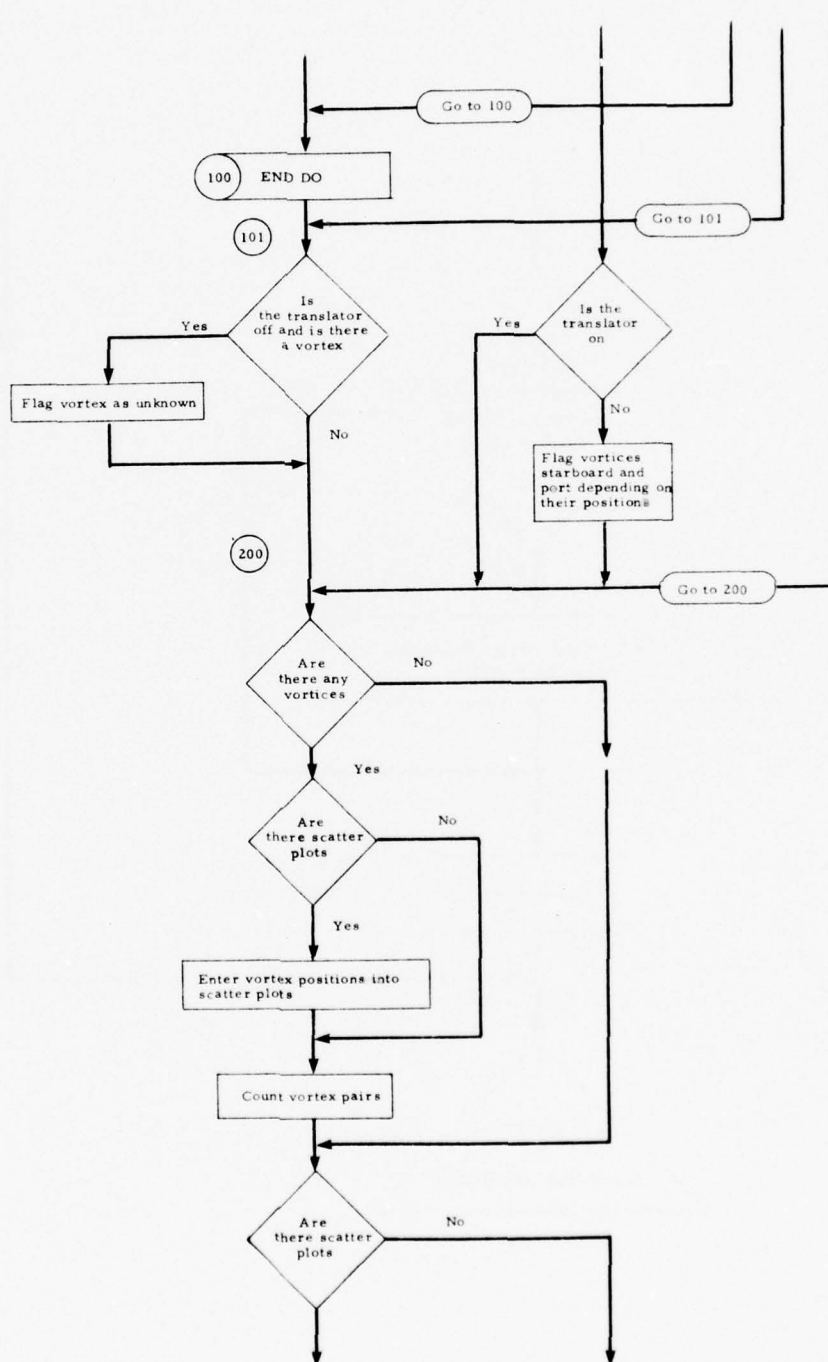

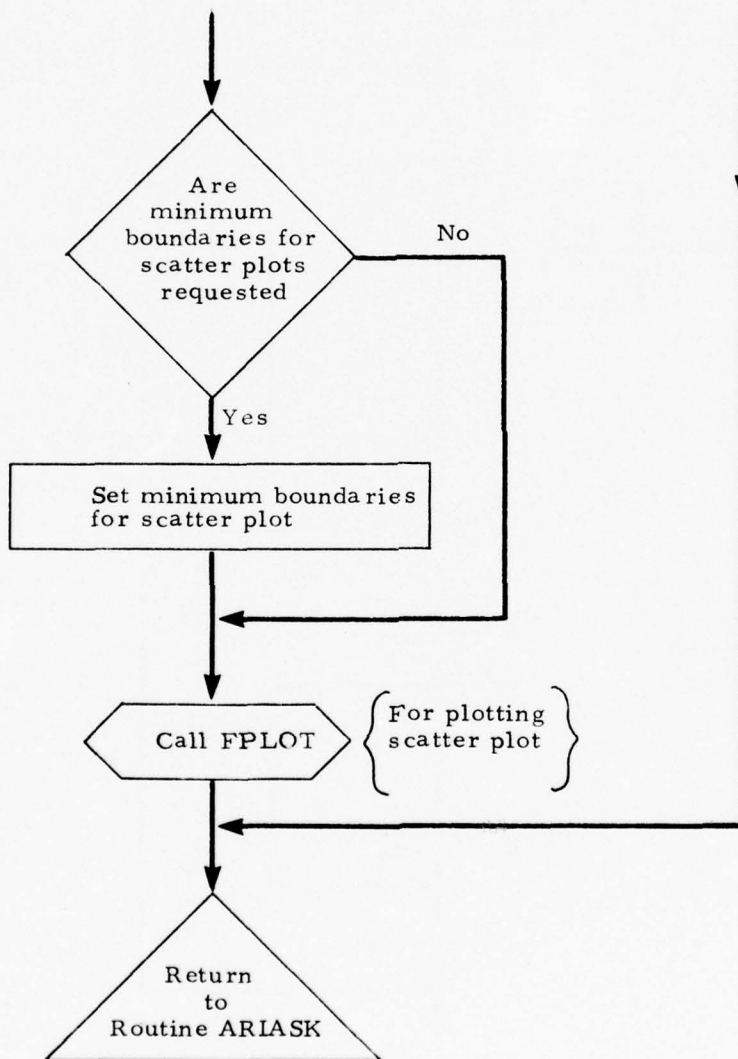

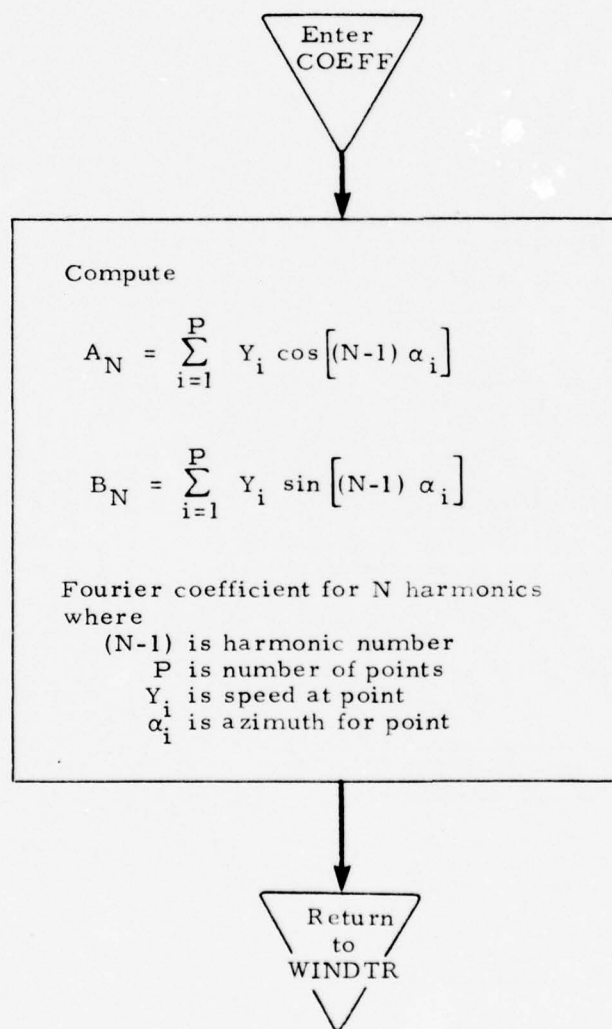

# ROUTINE COEFF

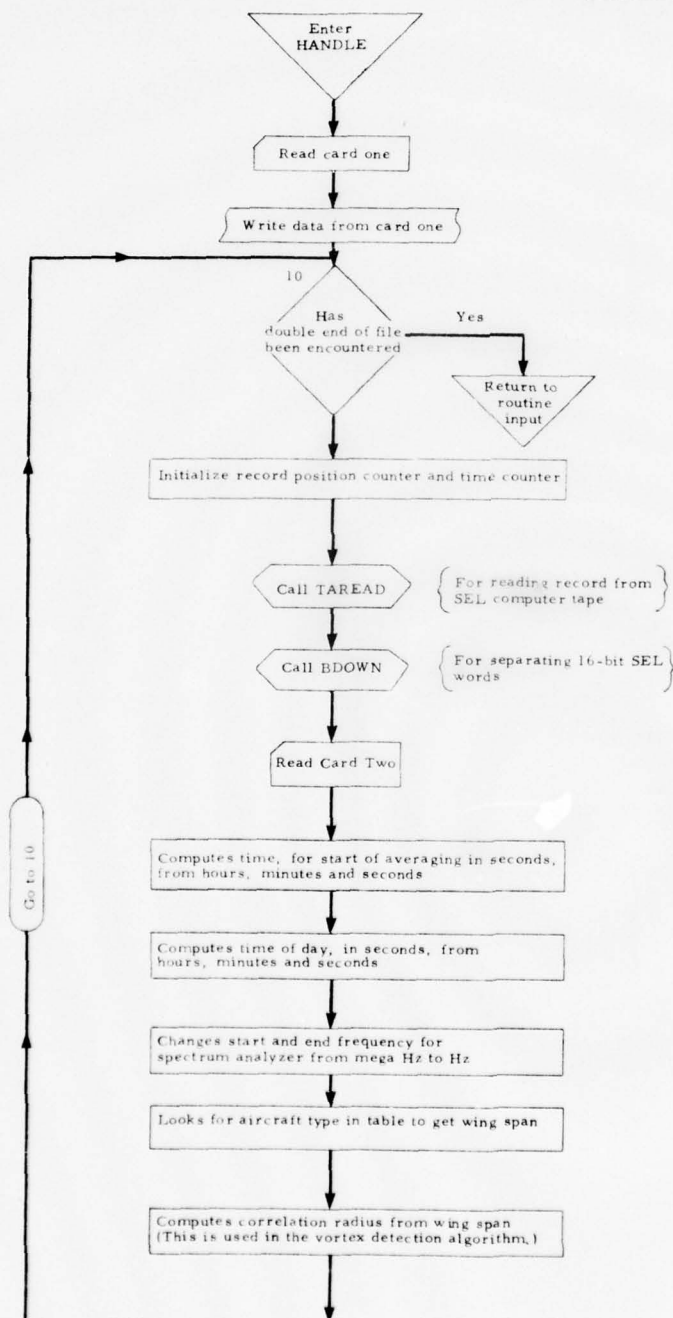

Computes Fourier coefficients  
of VAD signal

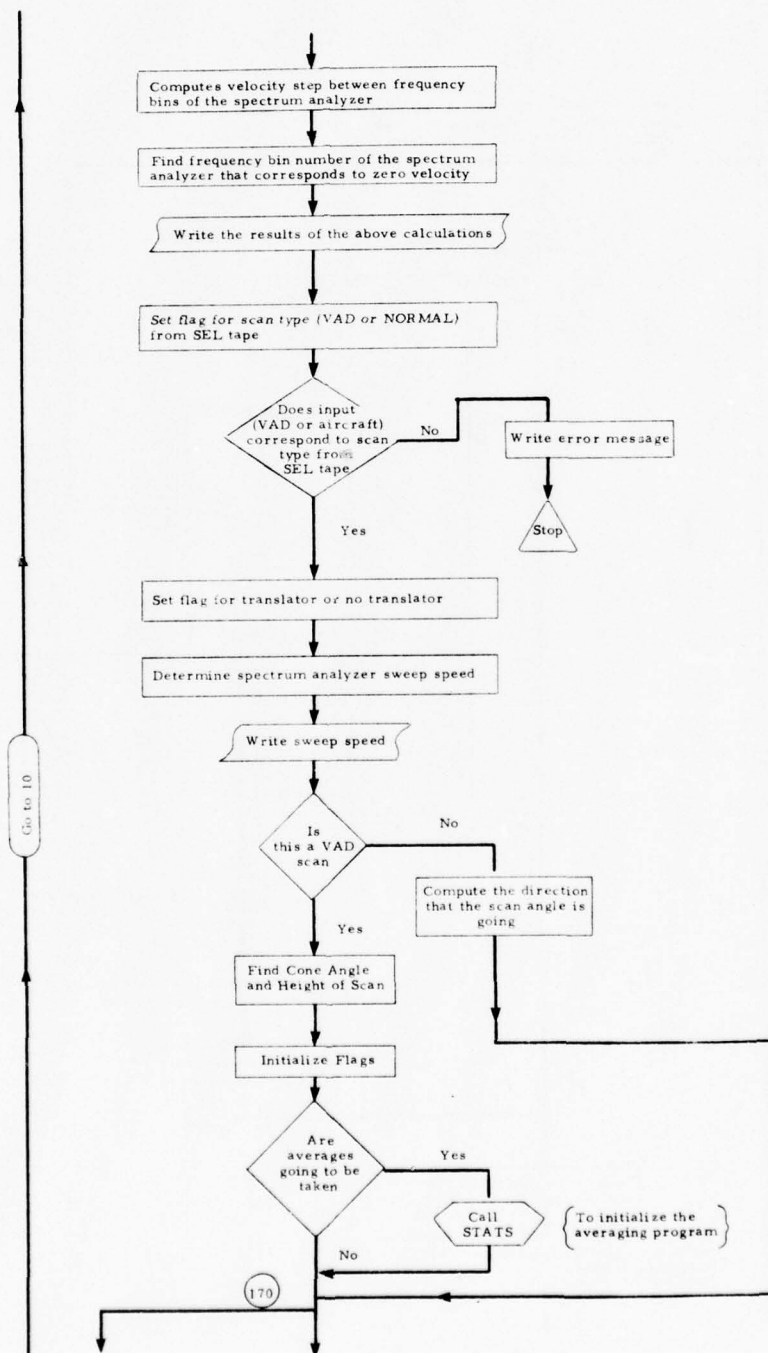

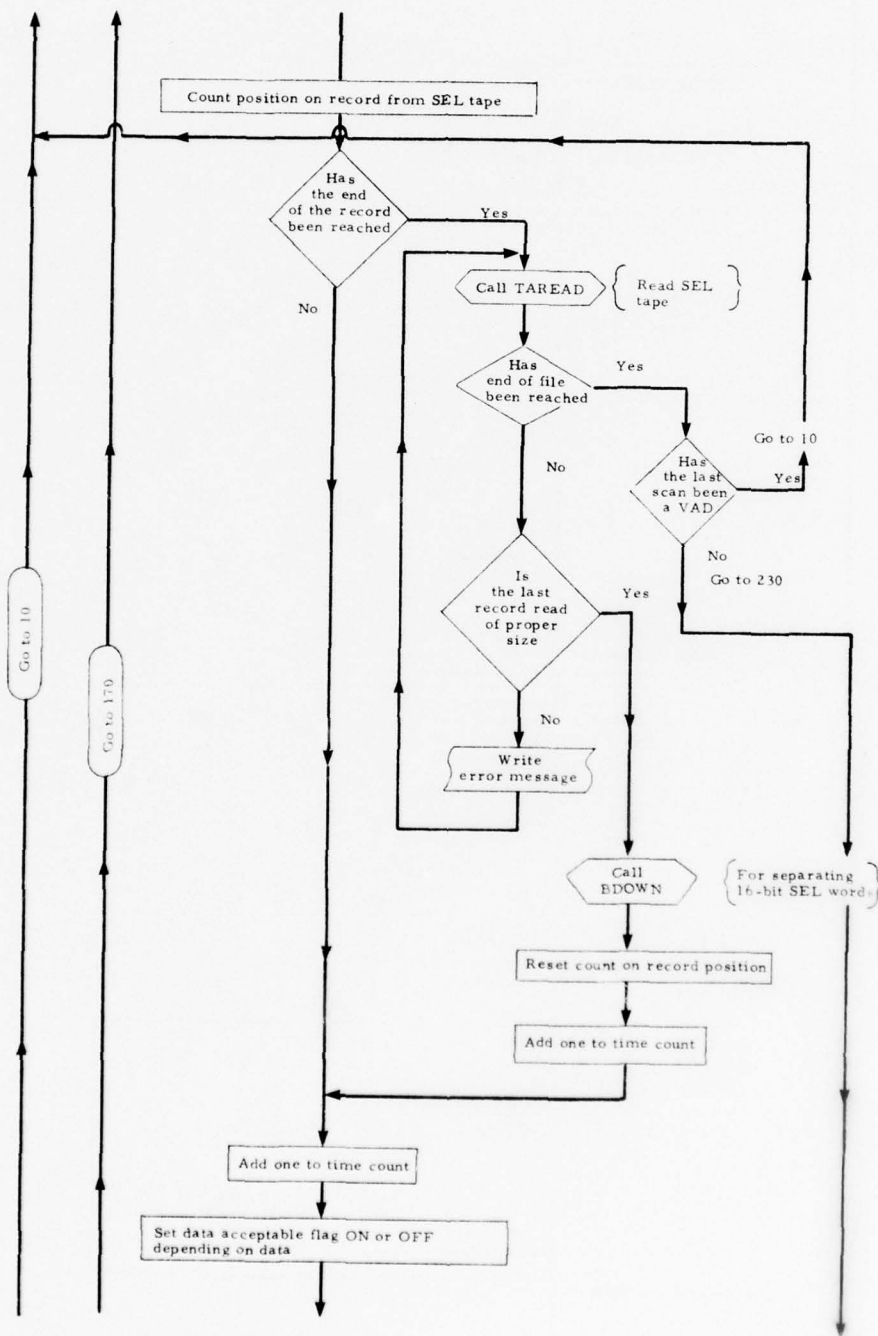

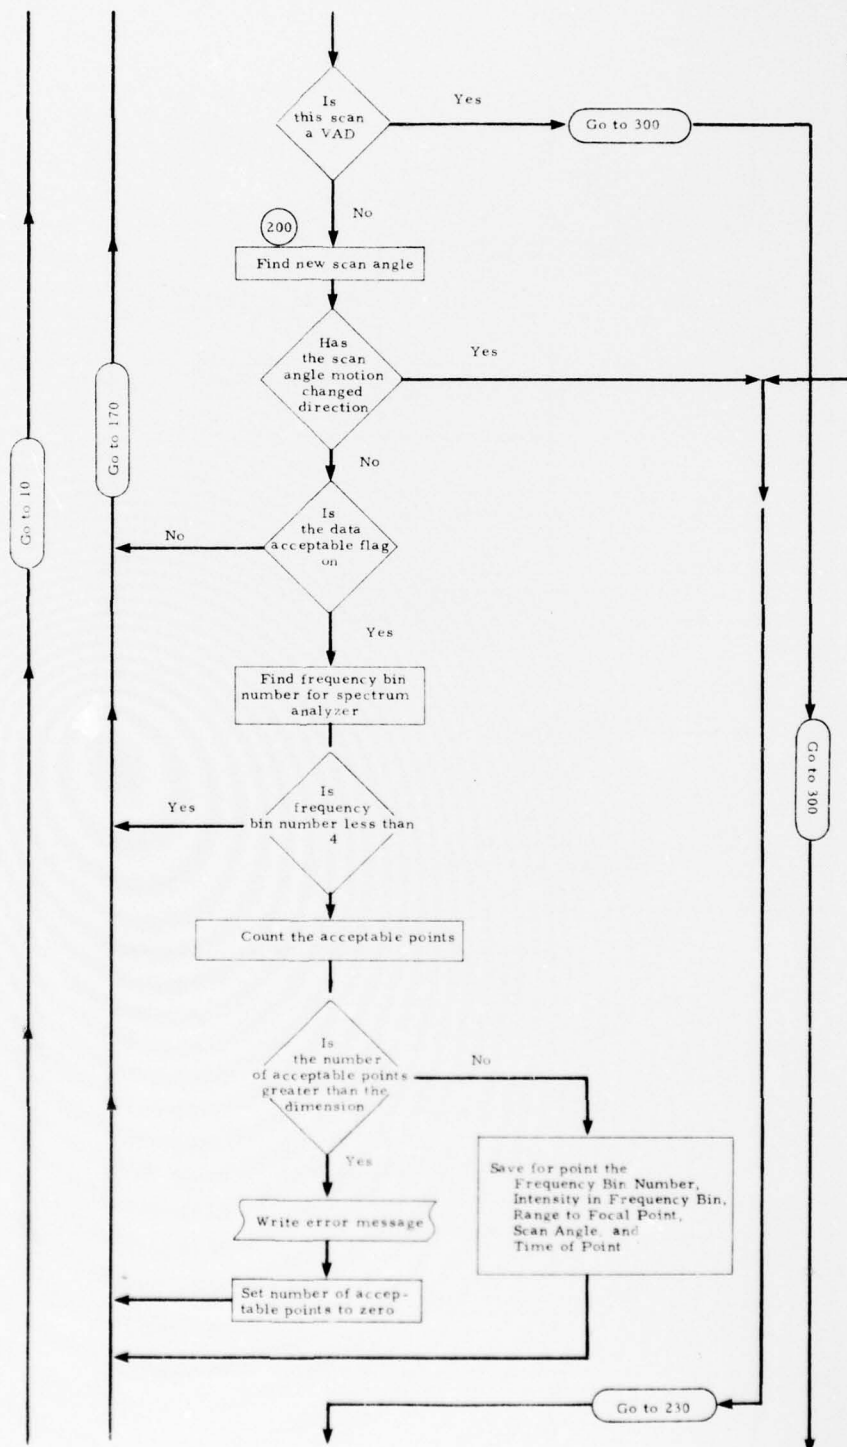

# ROUTINE HANDLE

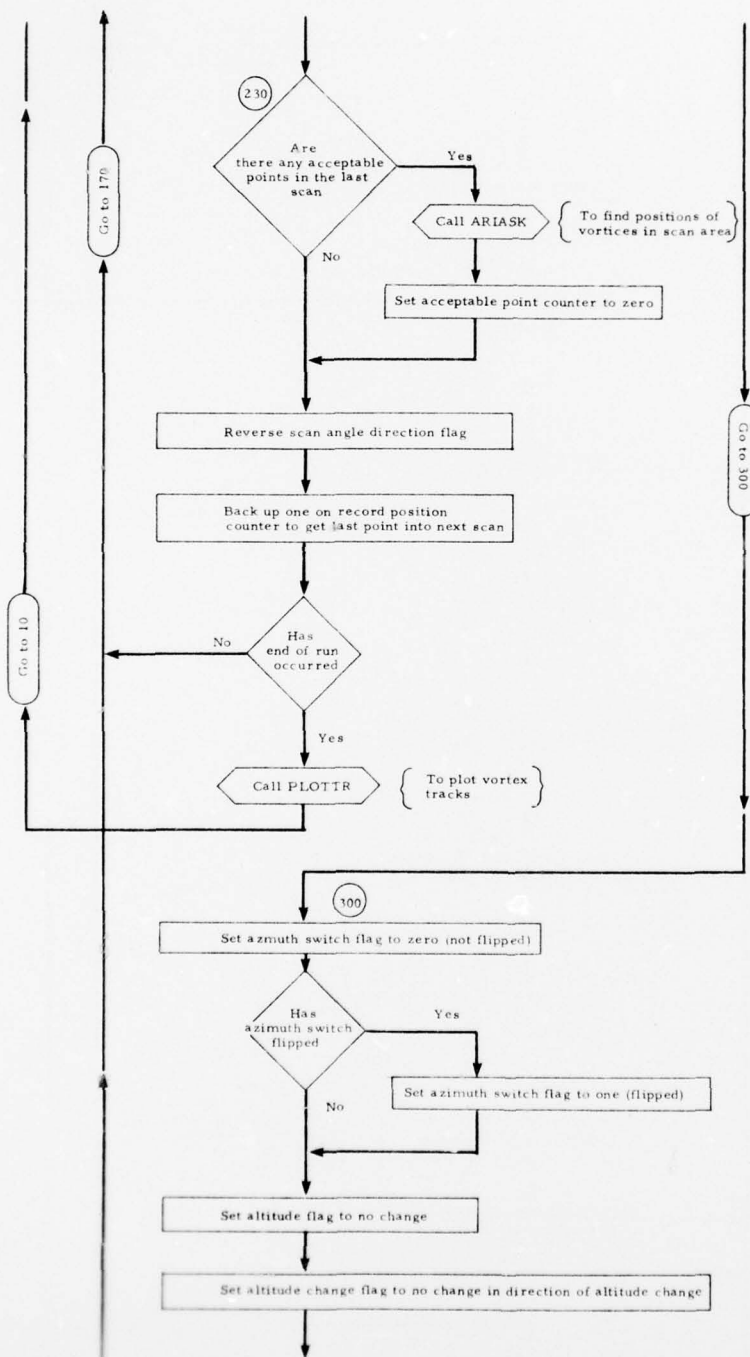

Main logic for program.  
Organizes data to be  
processed by other routines.

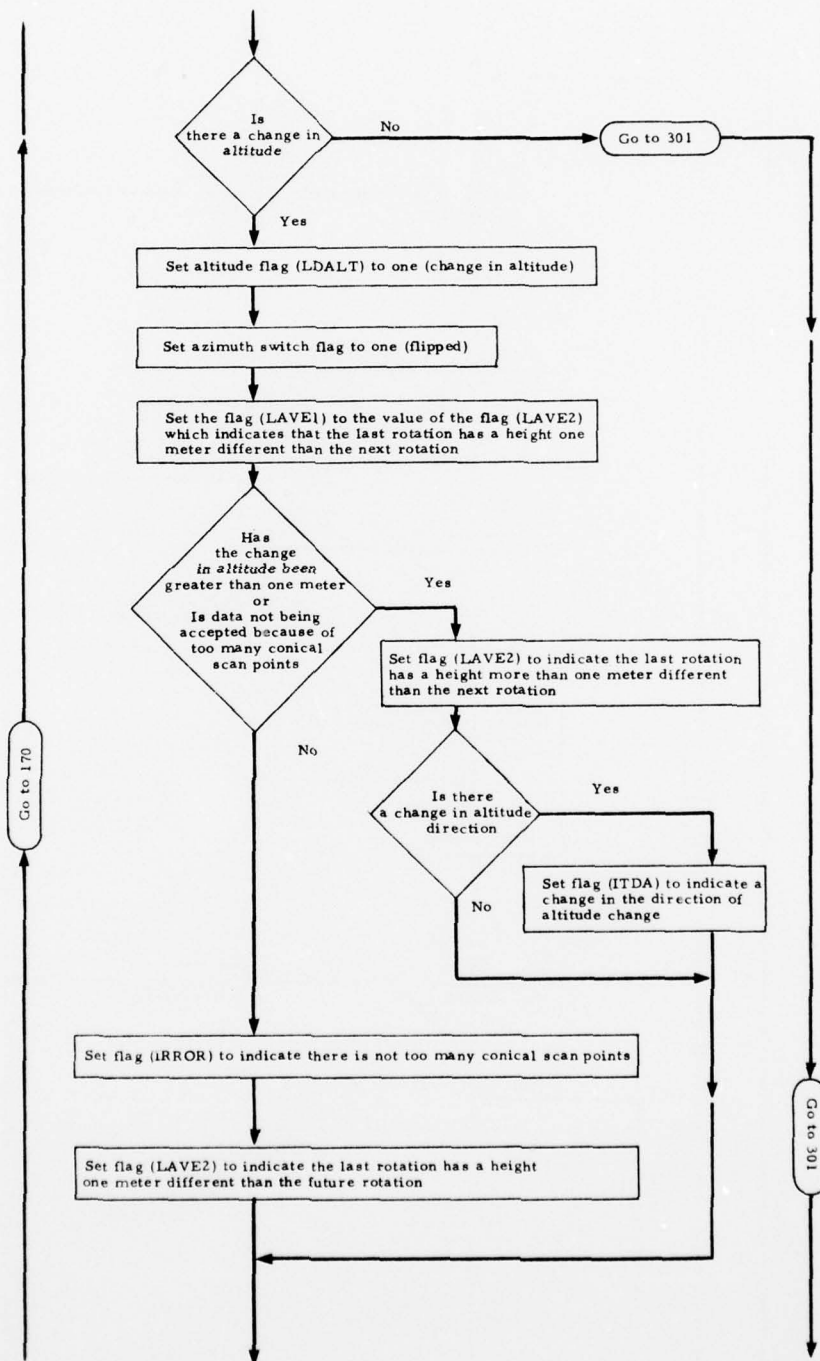

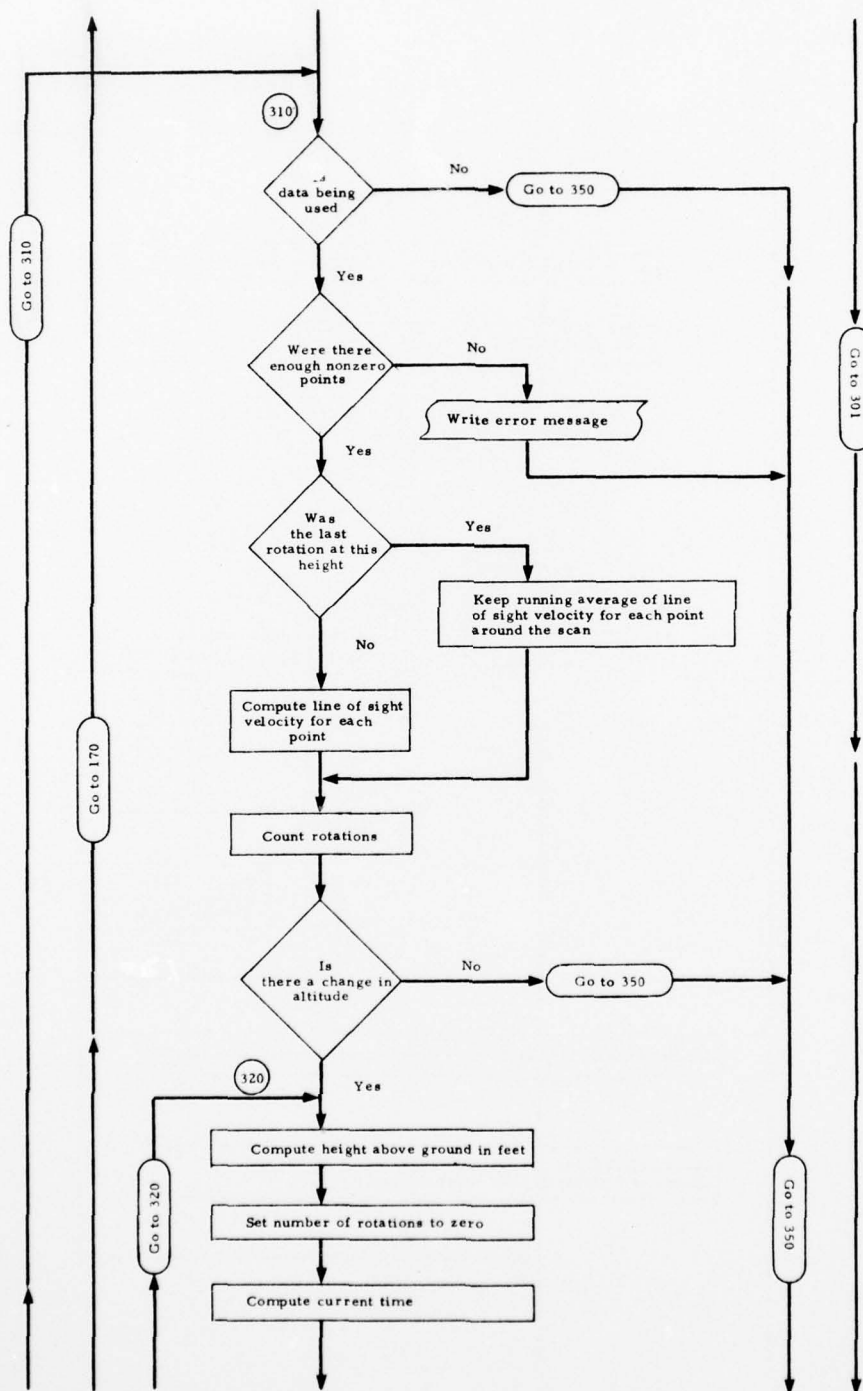

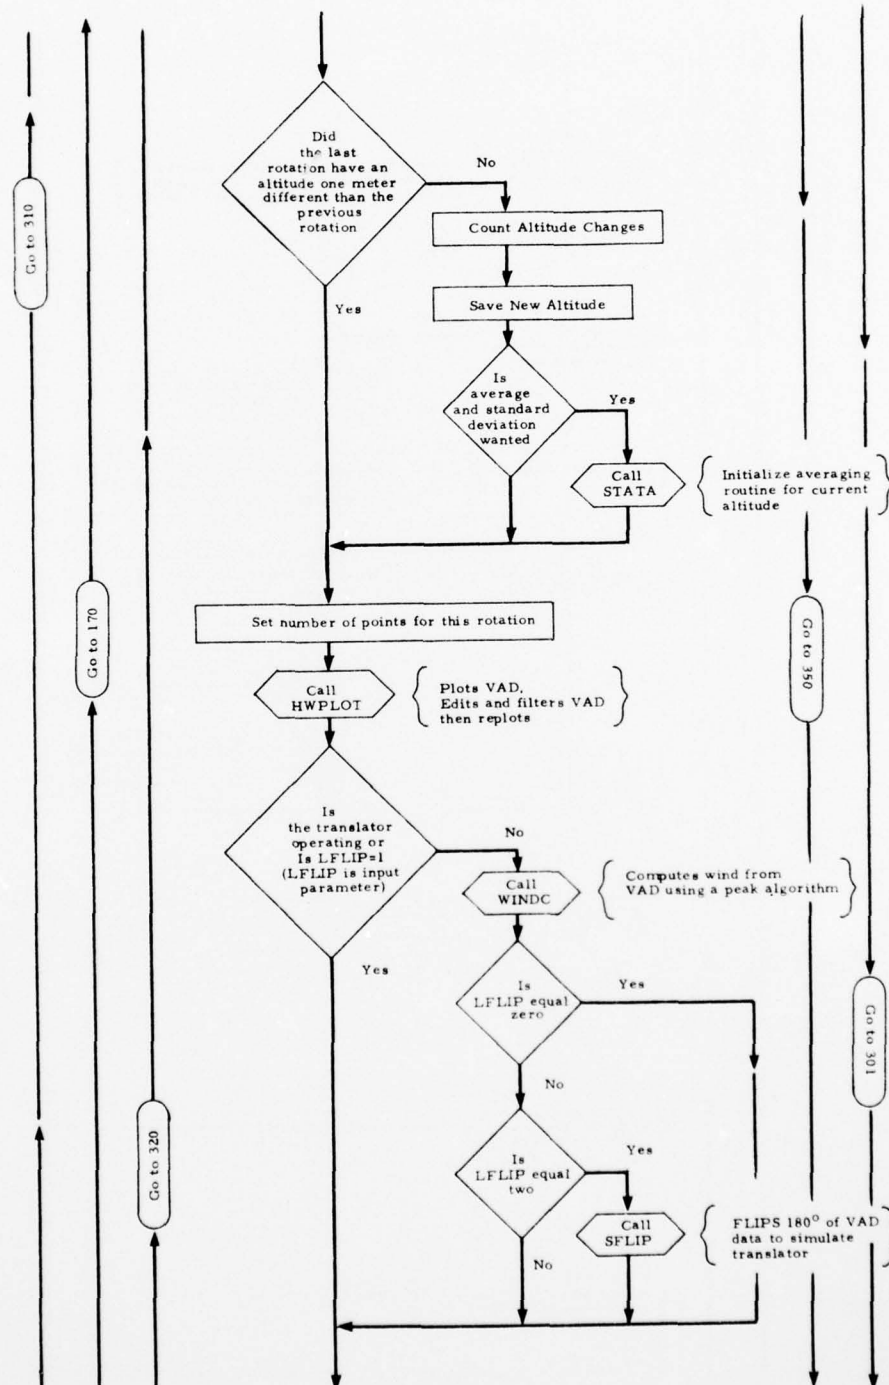

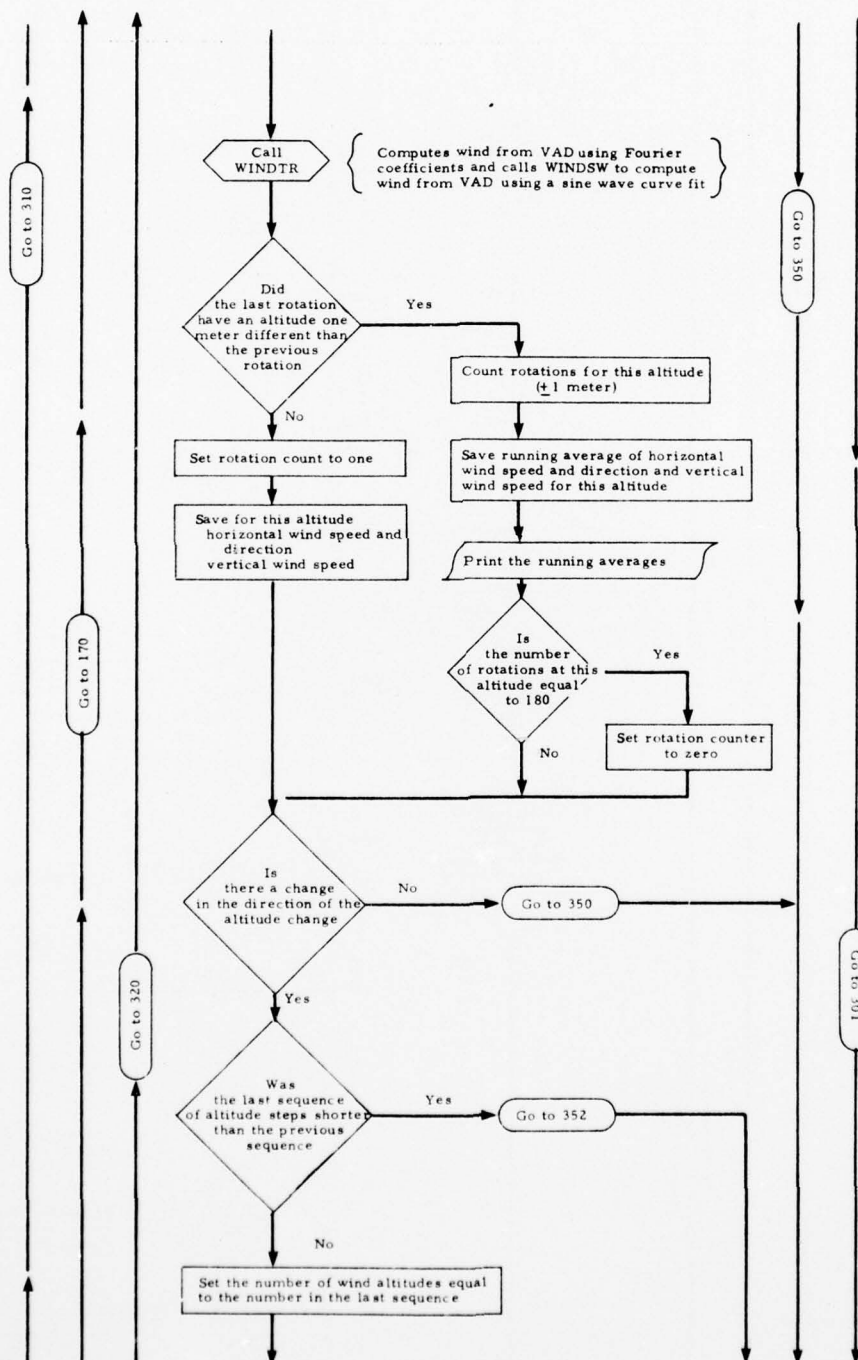

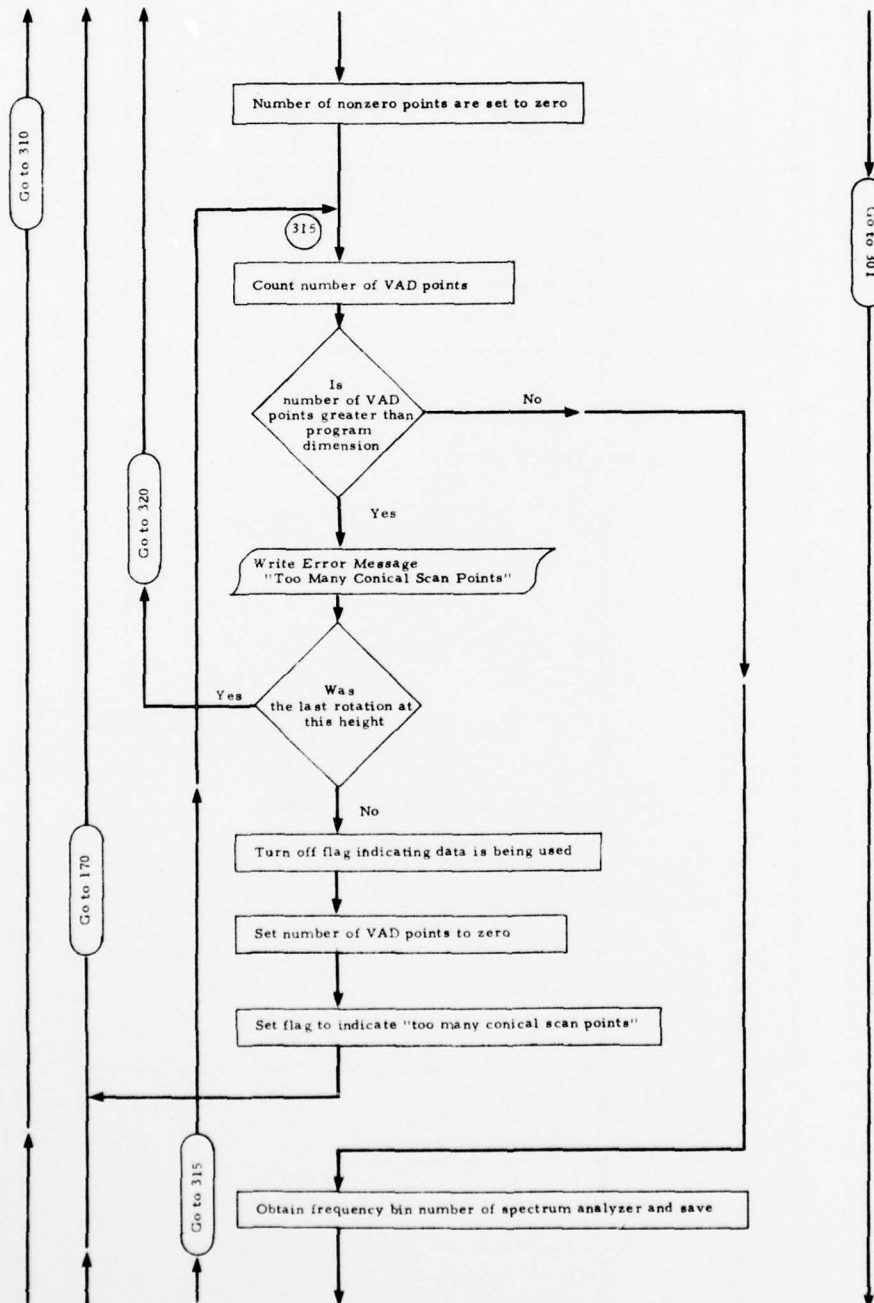

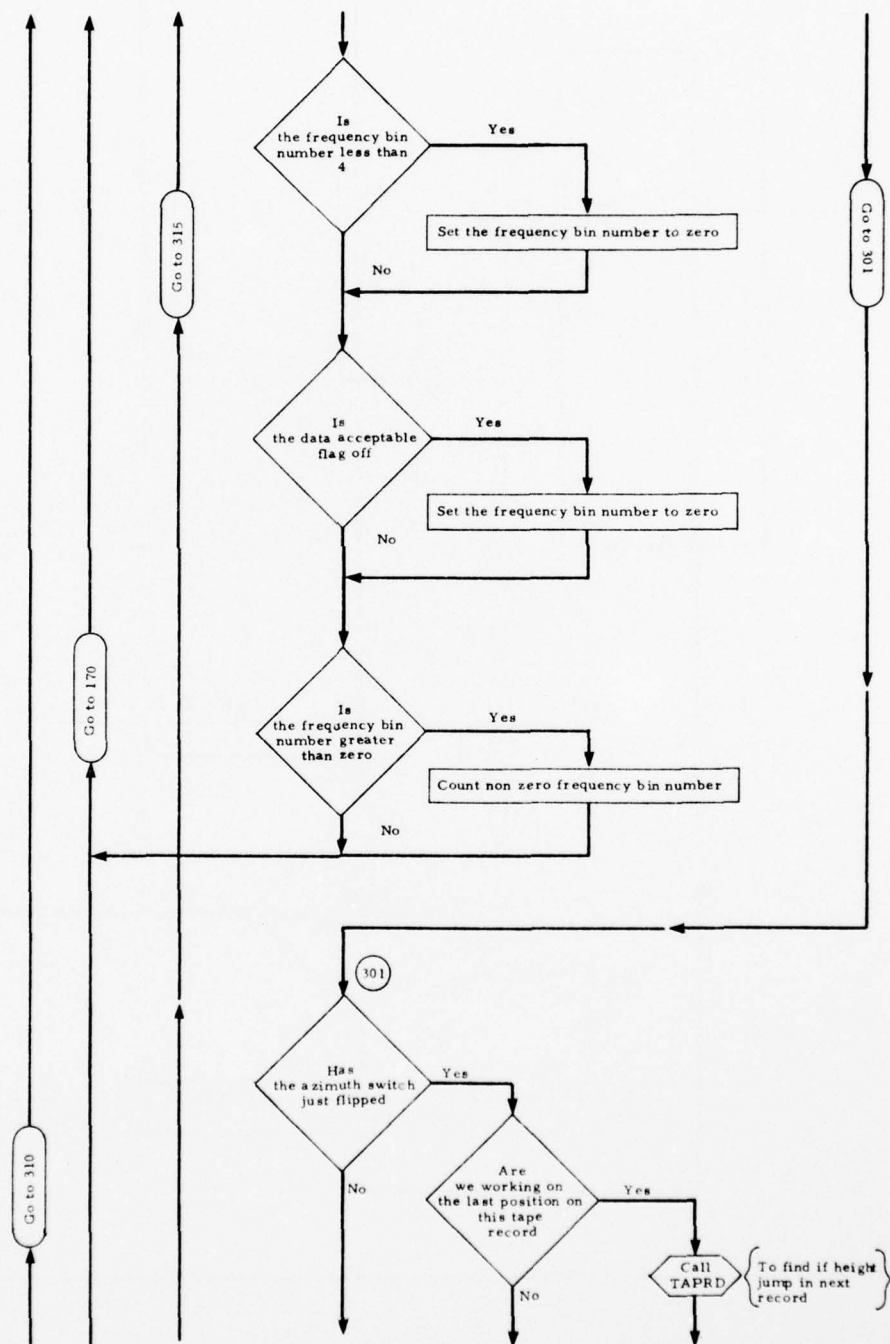

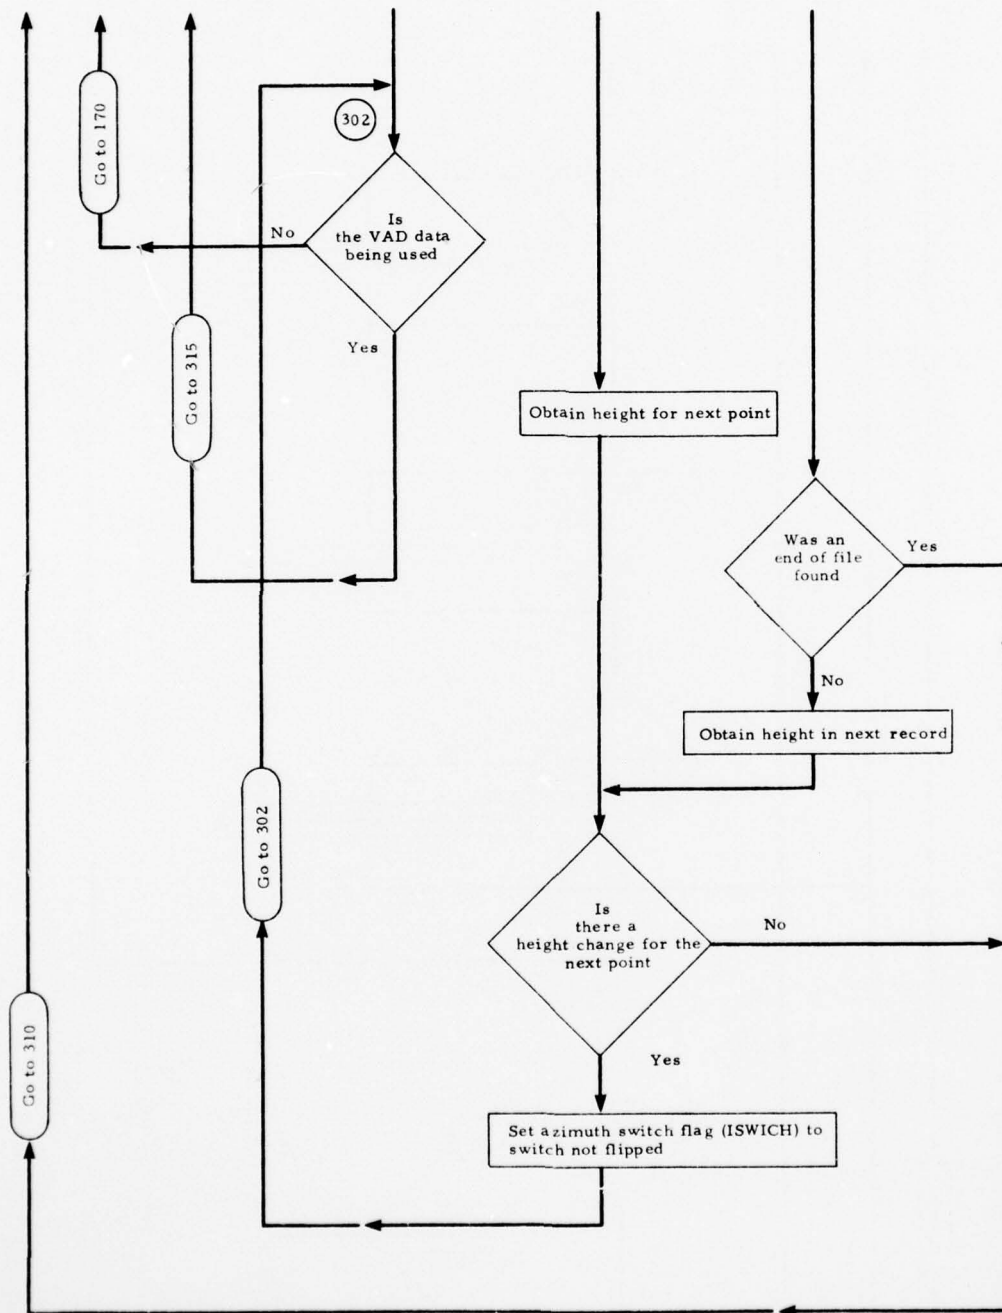

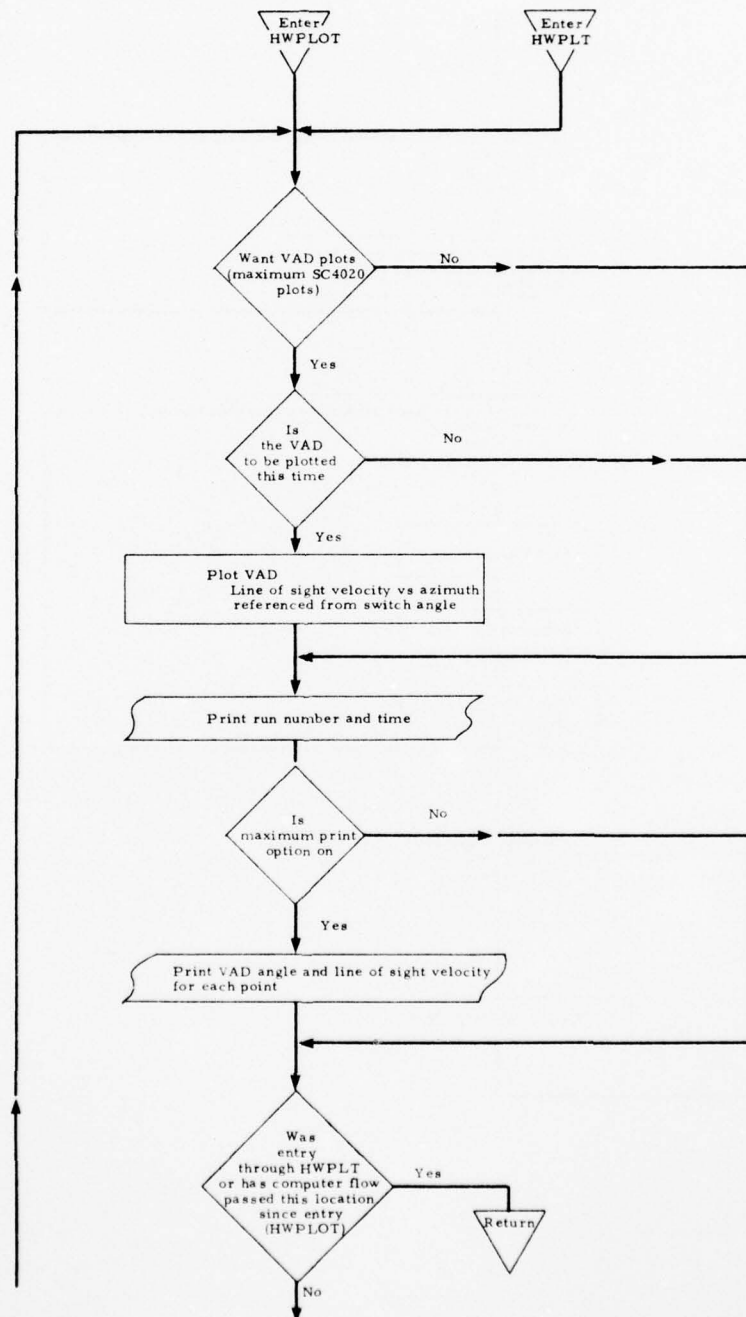

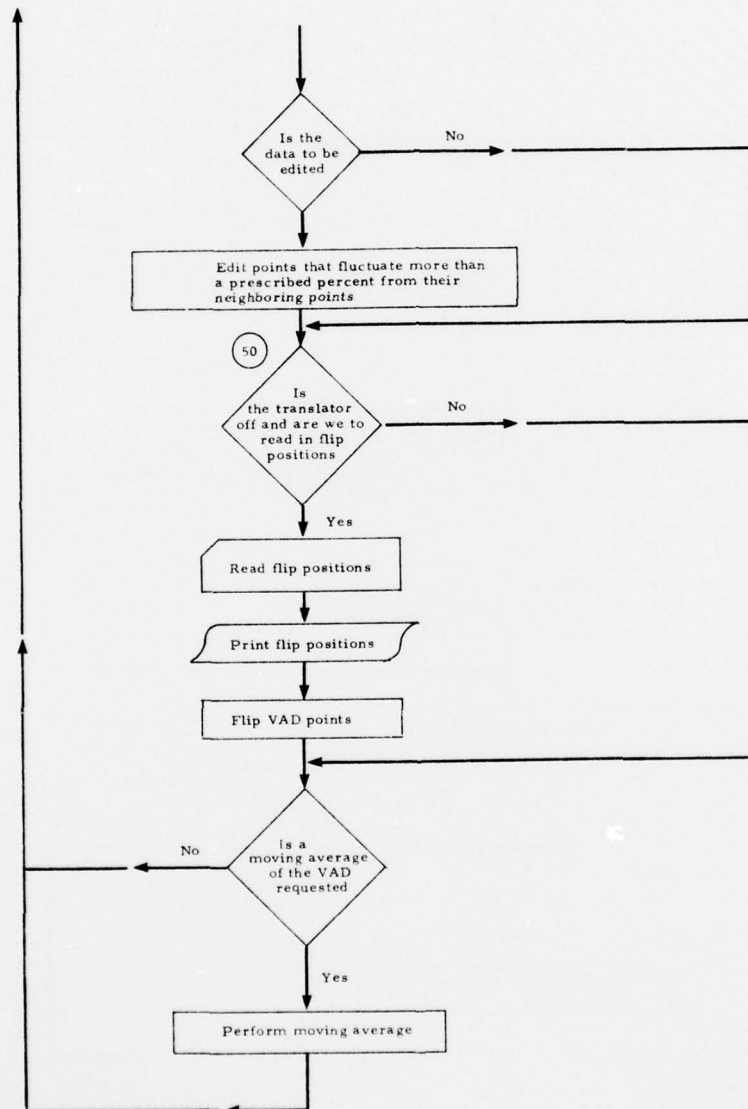

# ROUTINE HWPLOT

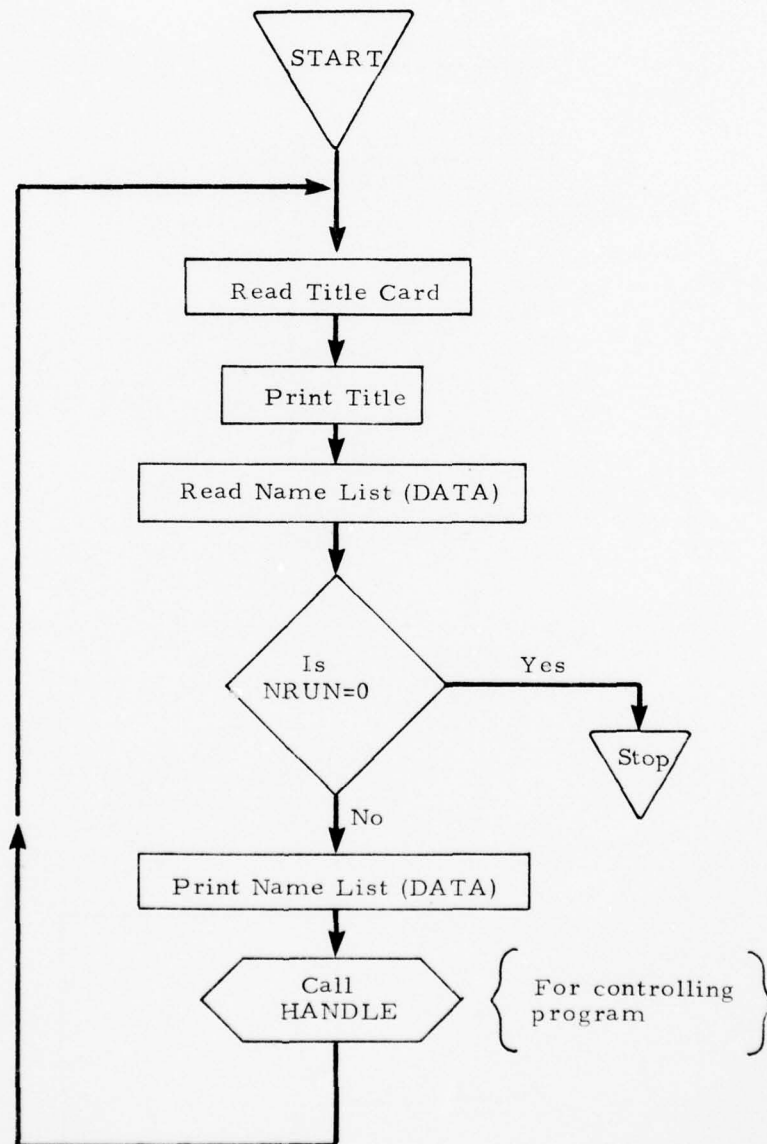

Plots VAD on SC4020 plotter  
(Also edits and smooths data)

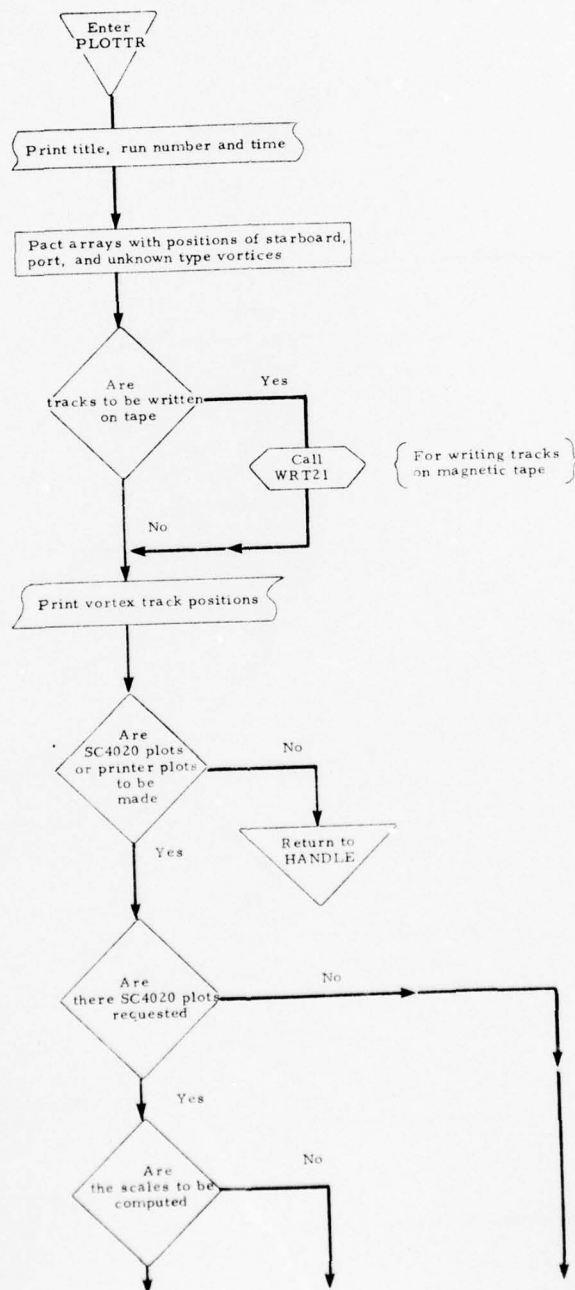

# ROUTINE INPUT

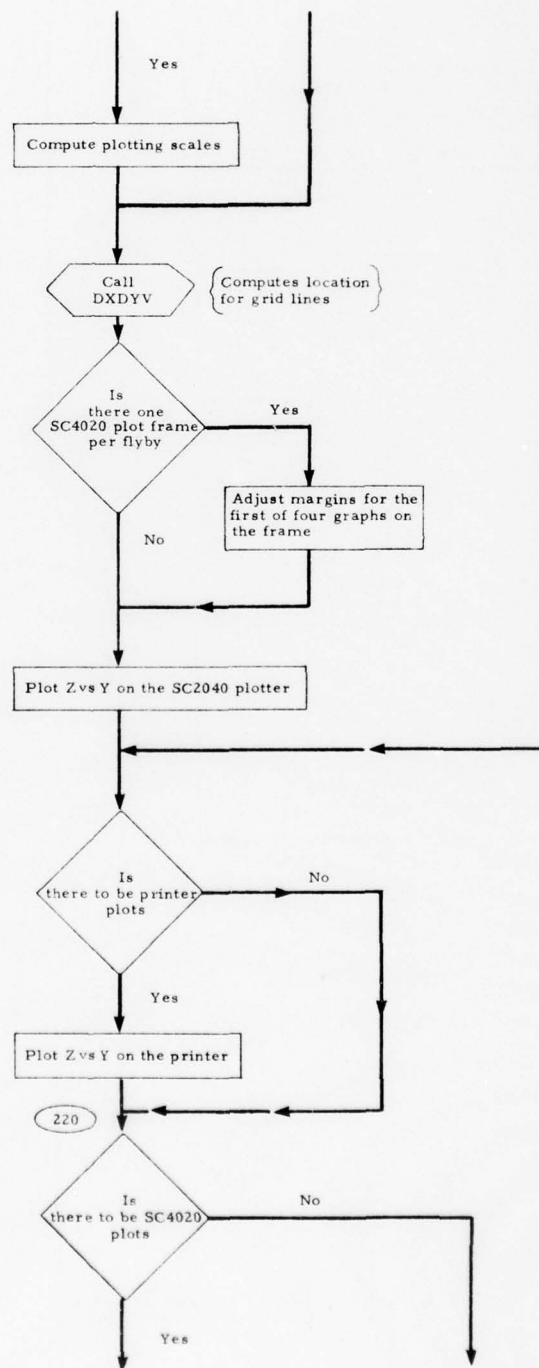

Read cards with parameters  
to direct program operation

# ROUTINE PLOTTR

Plots vortex tracks  
on SC4020 plotter

# ROUTINE PROFIL

Plots wind profile as a function of height on the SC4020 plotter

ROUTINE SFLIP

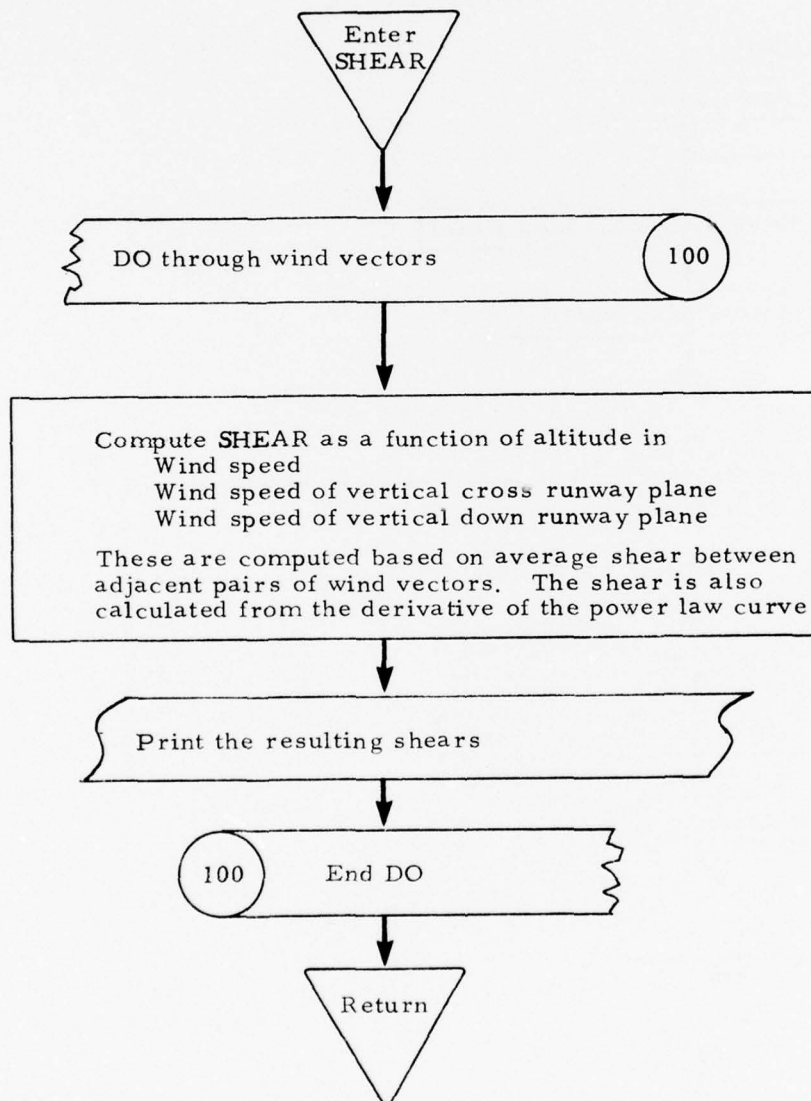

Flips sign of speed  
of VAD to simulate  
translator

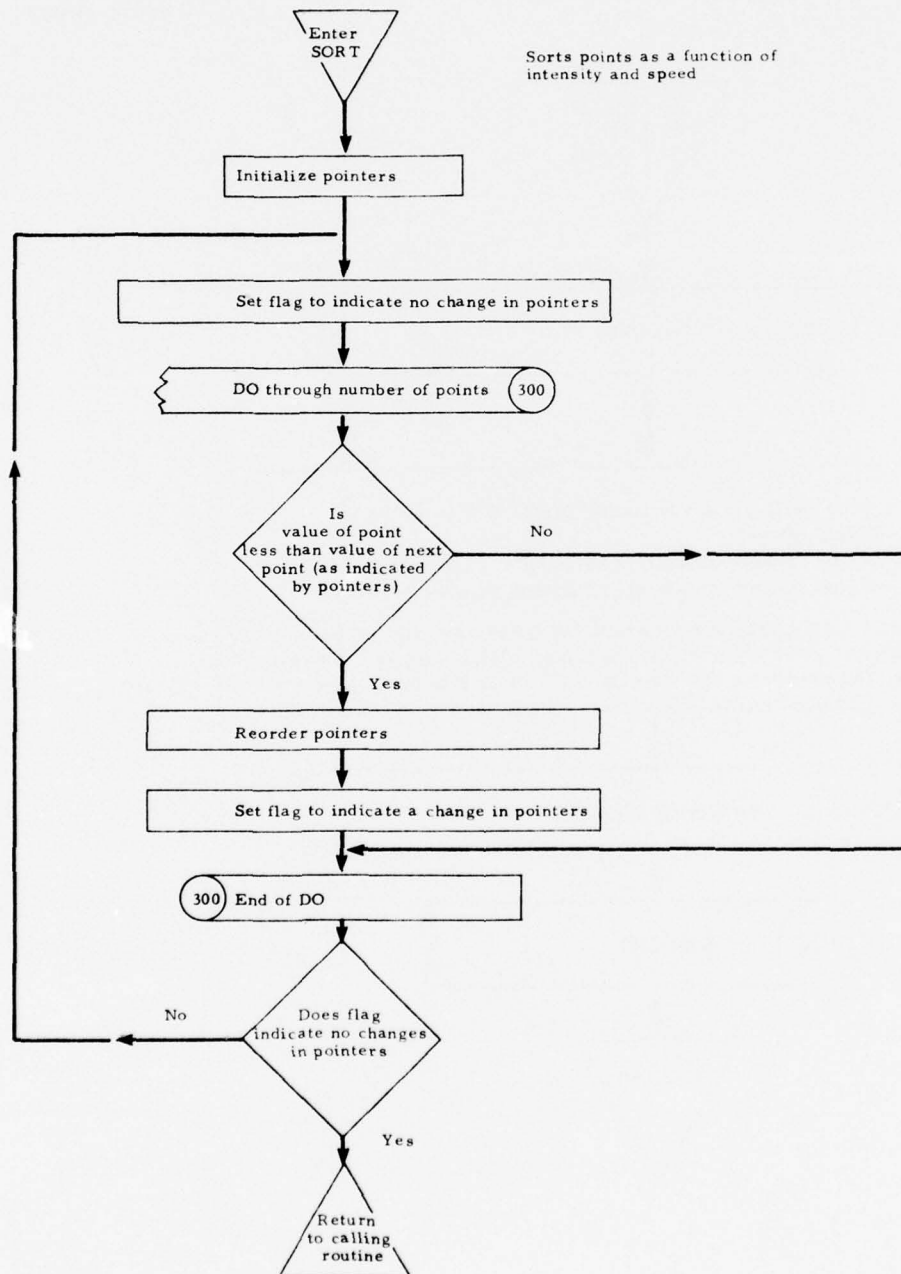

# ROUTINE SHEAR

Computes and prints  
wind shear

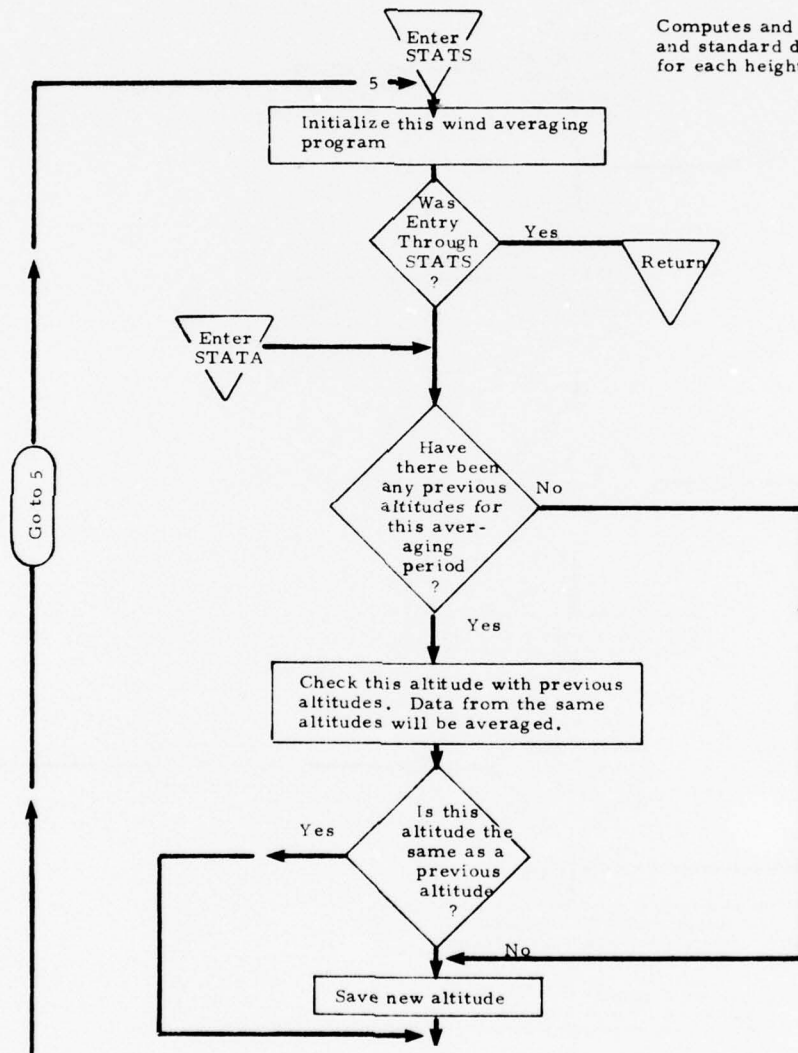

# ROUTINE SORT

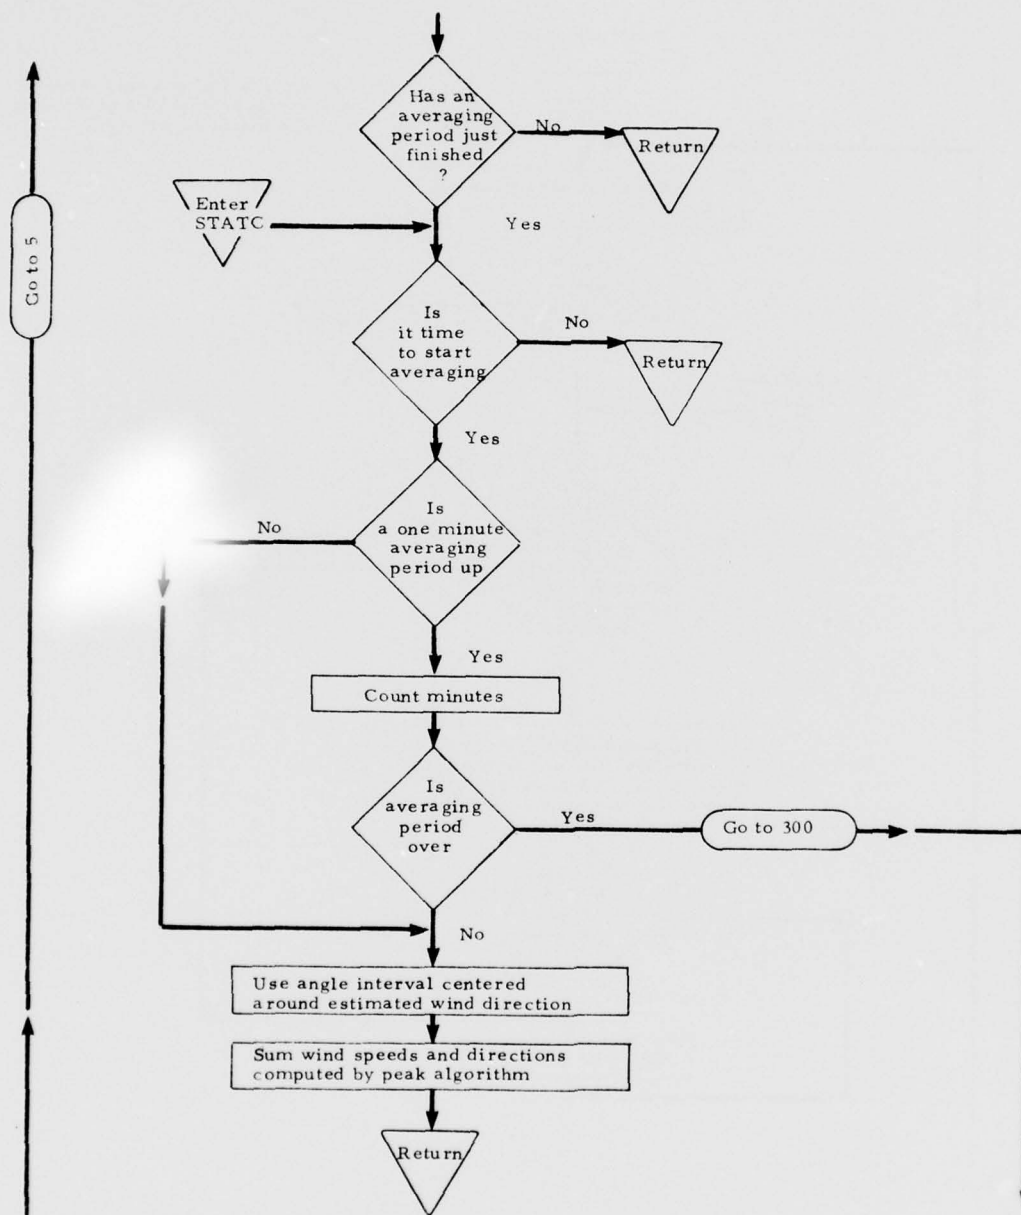

Sorts points as a function of  
intensity and speed

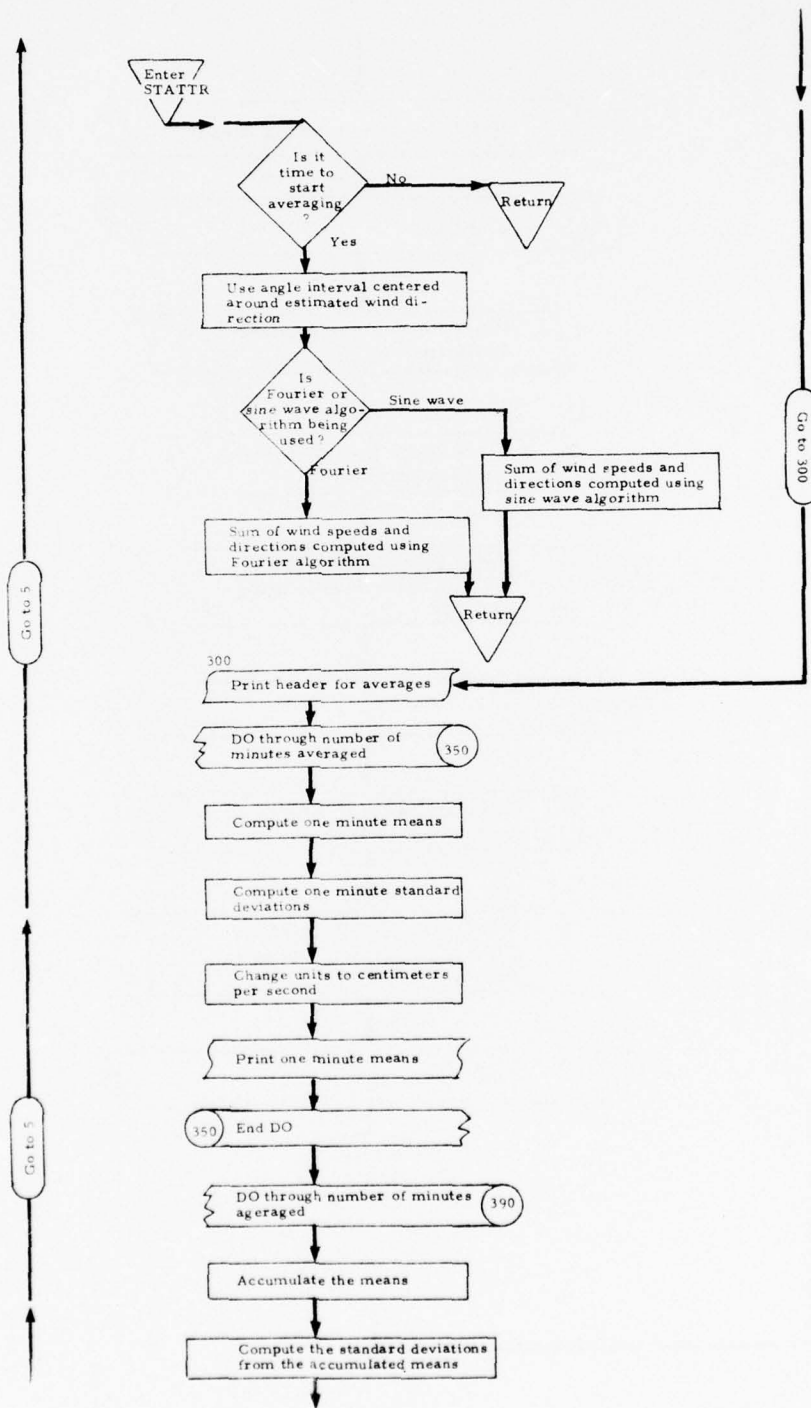

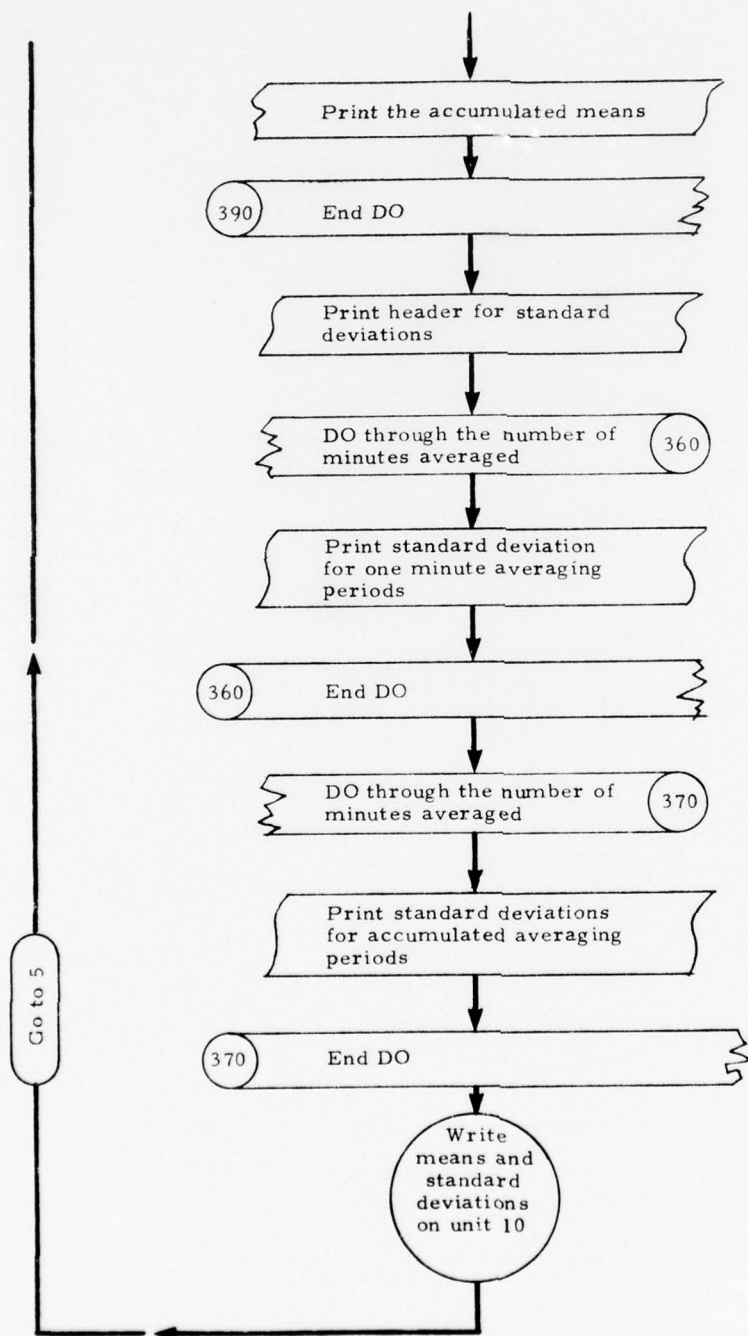

# ROUTINE STATS

Computes and prints the averages and standard deviations of the wind for each height represented

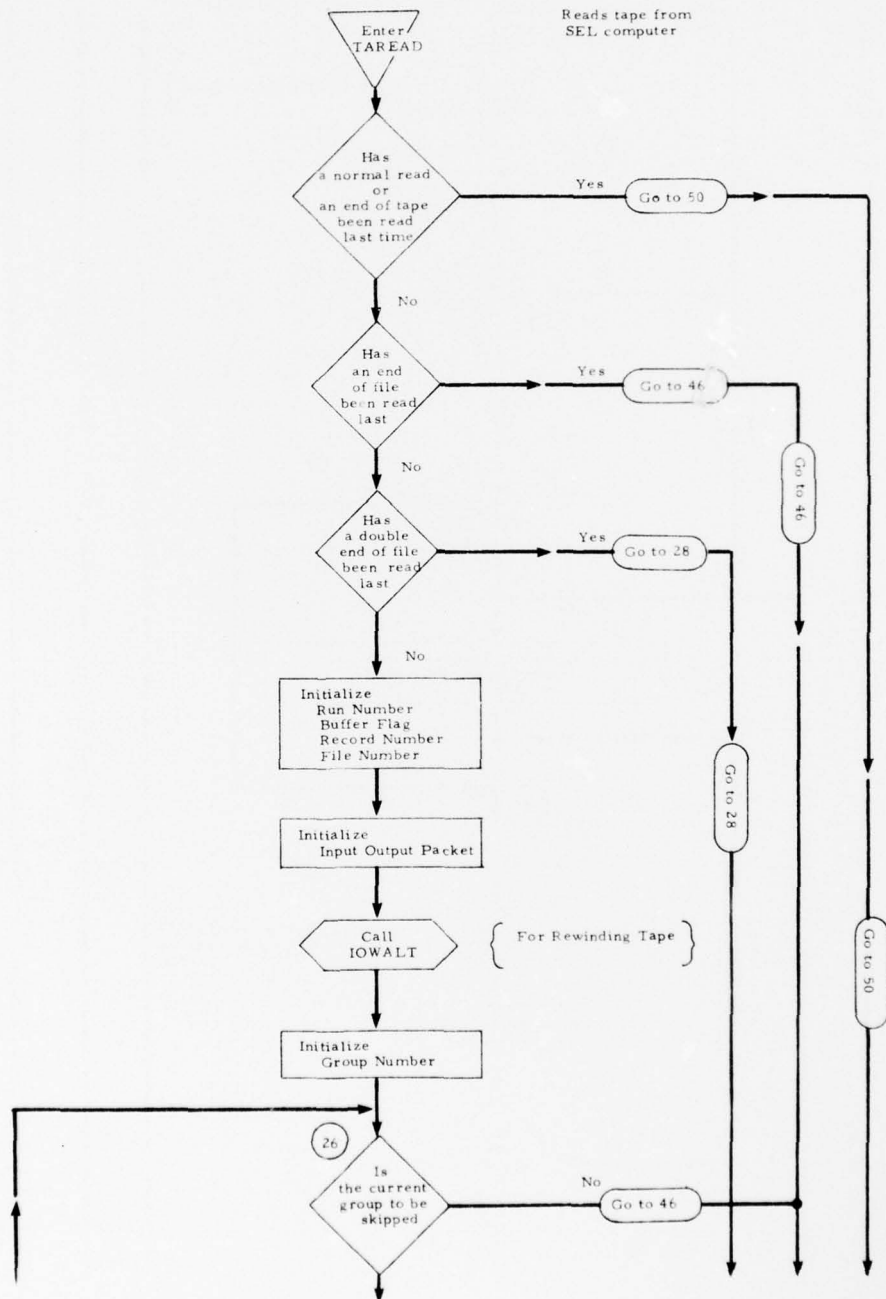

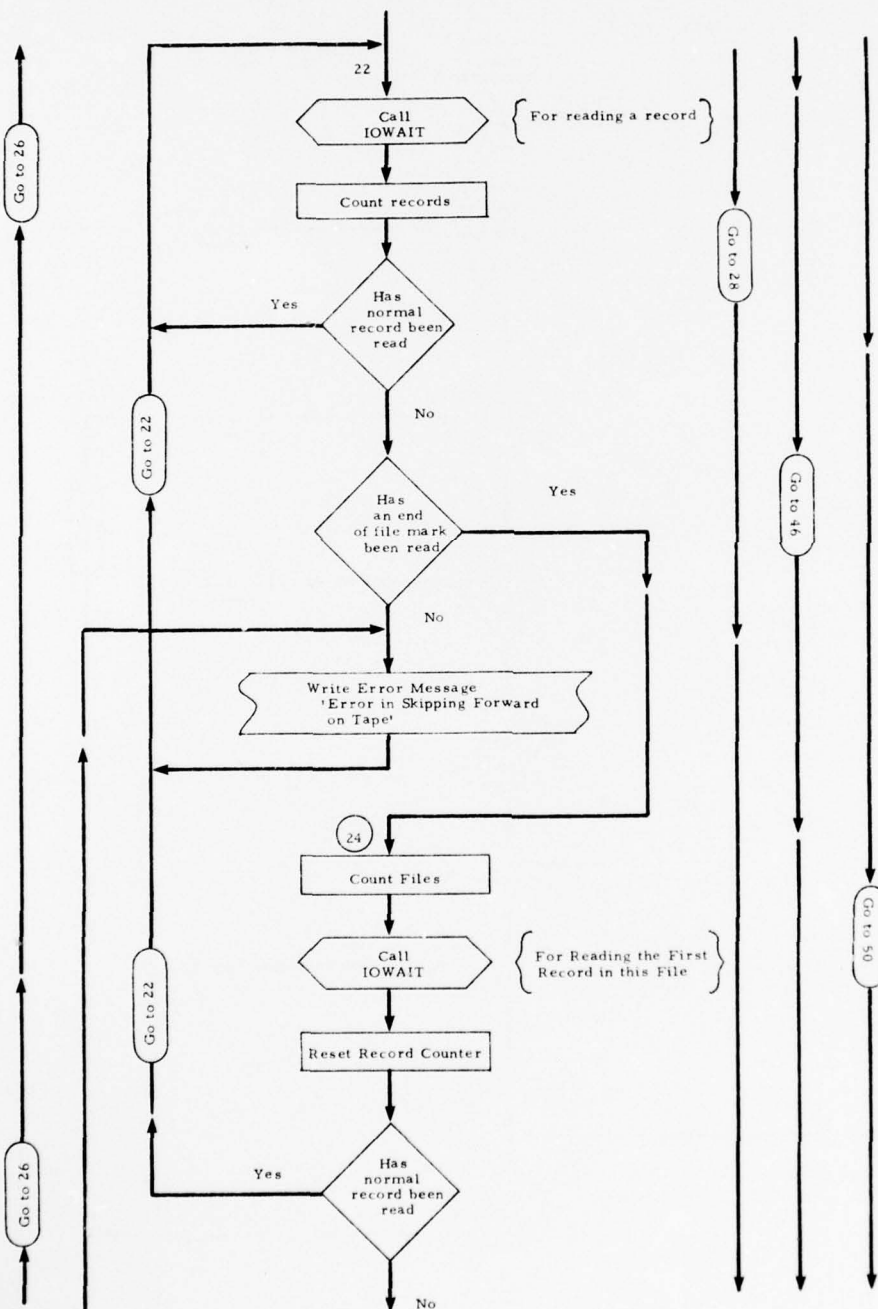

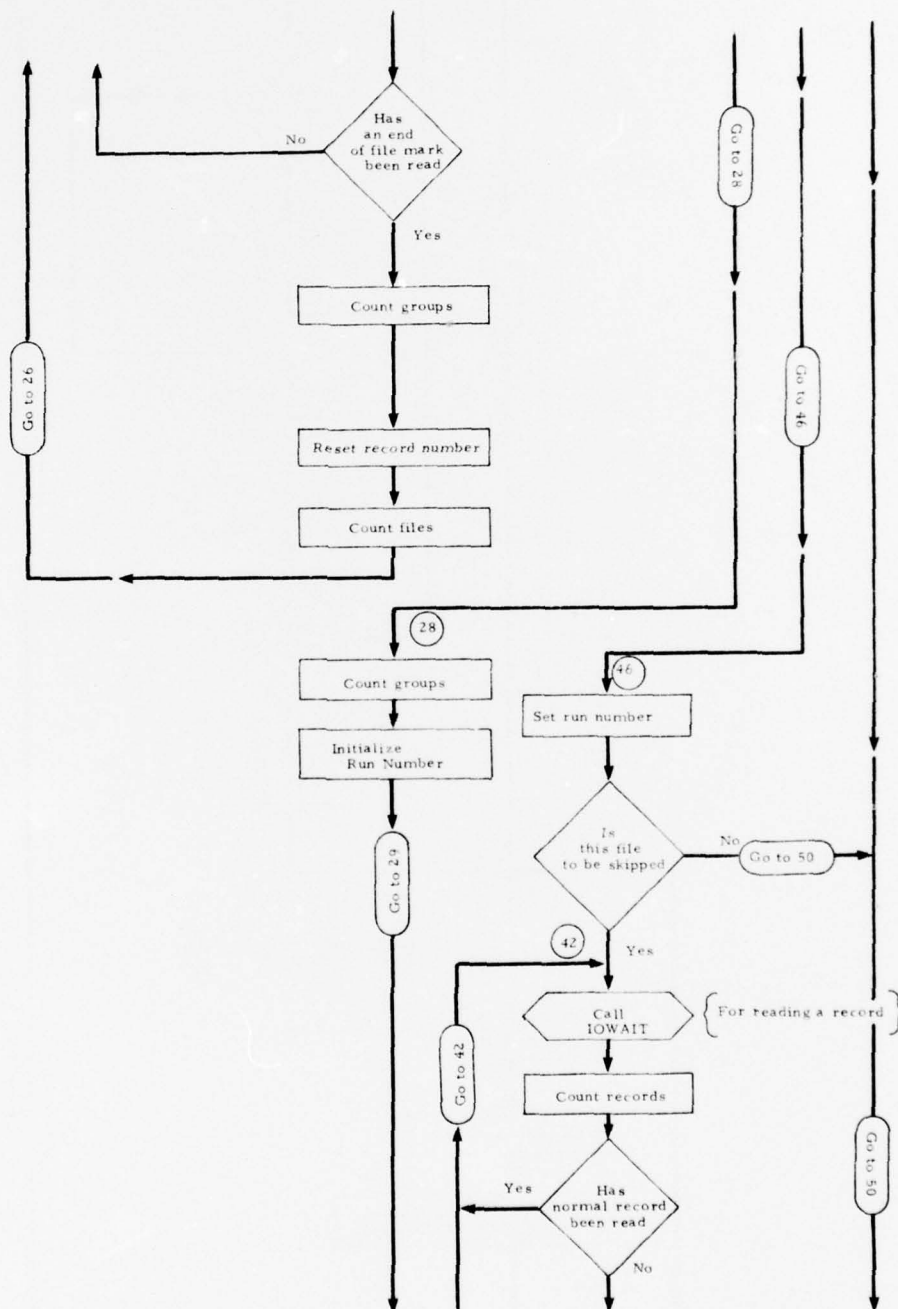

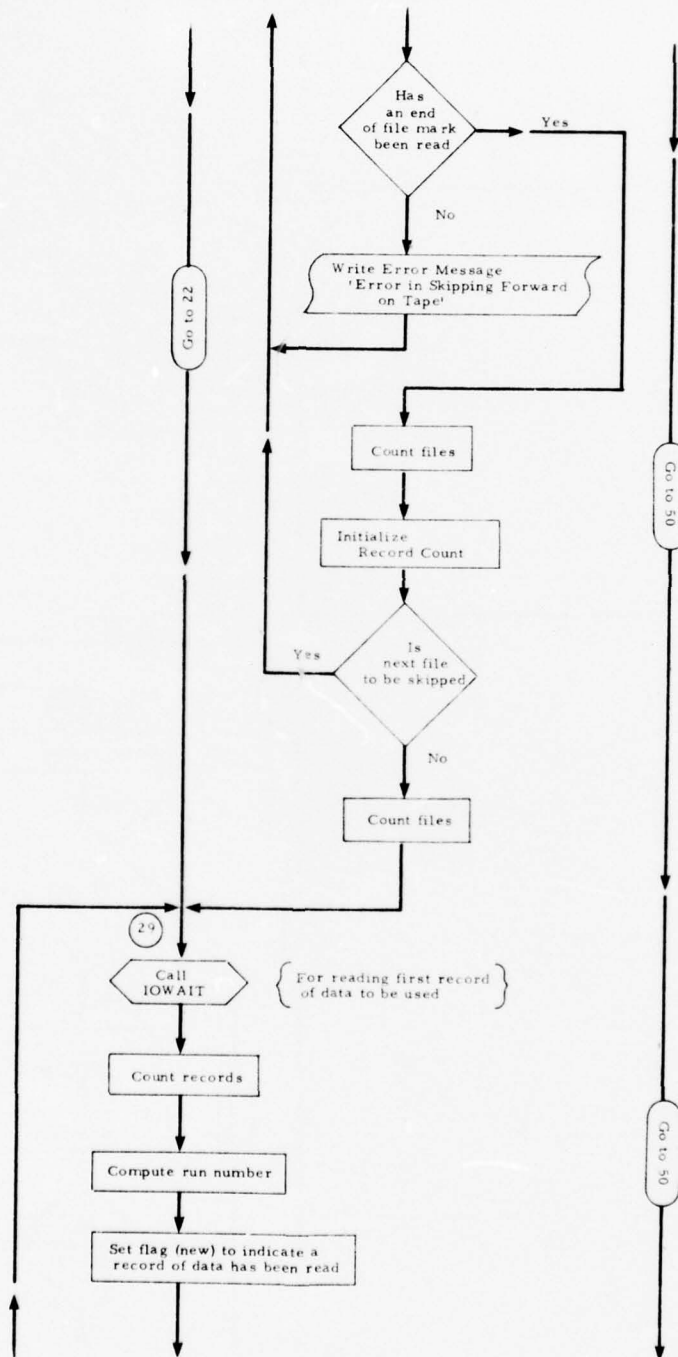

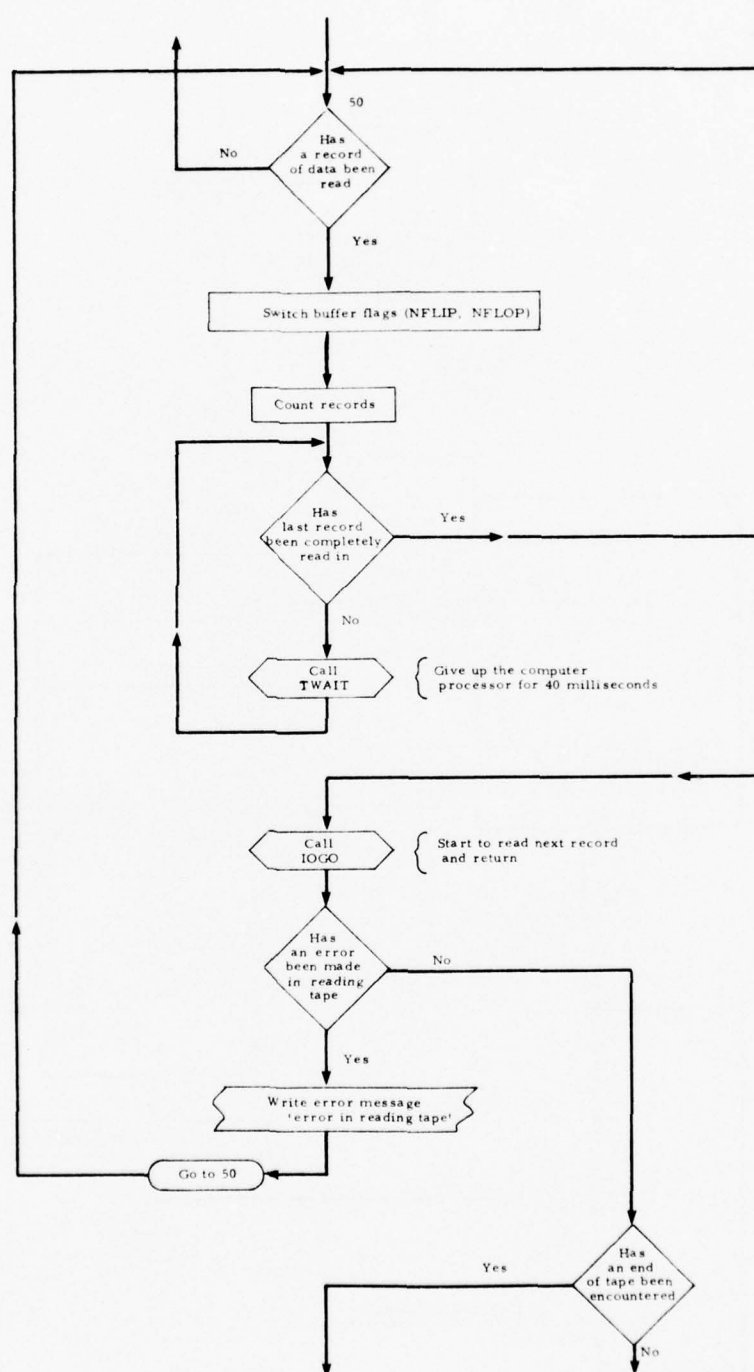

# ROUTINE TAREAD

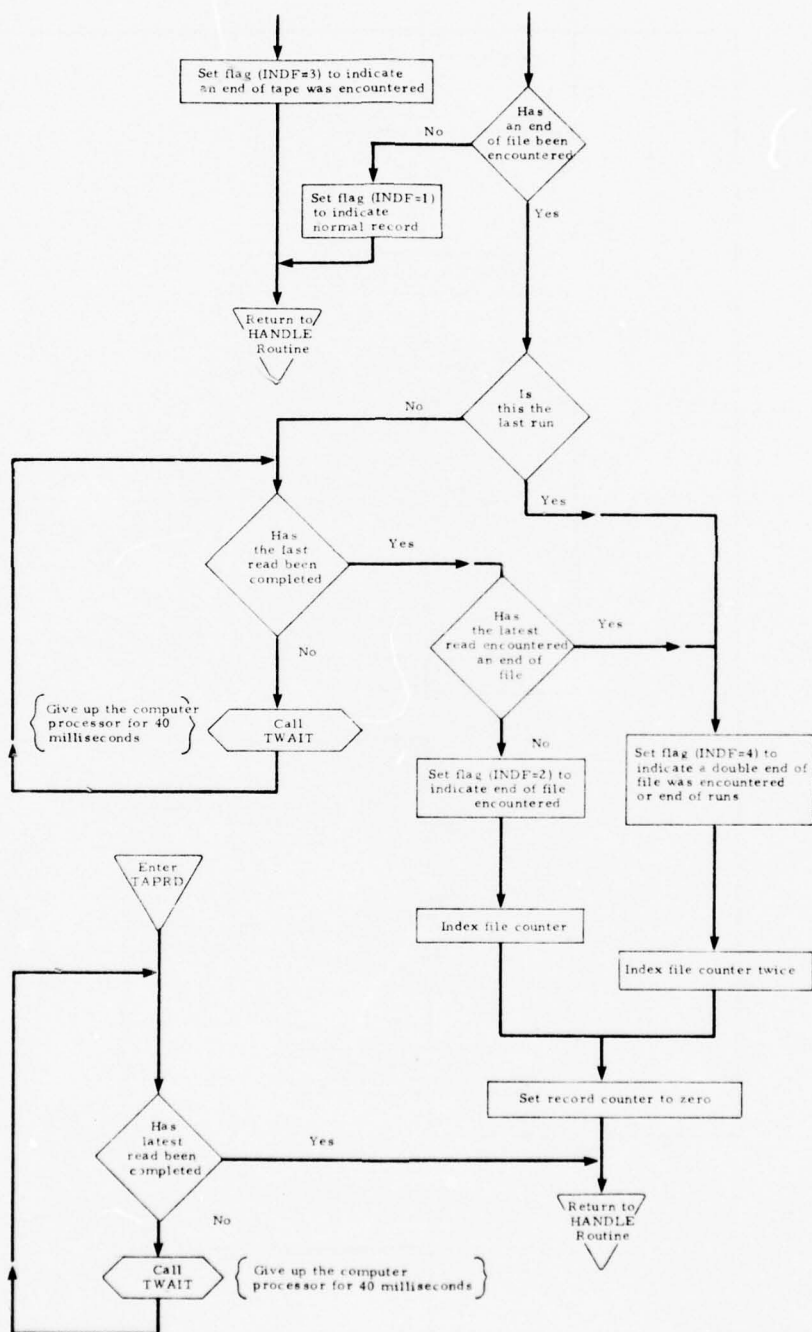

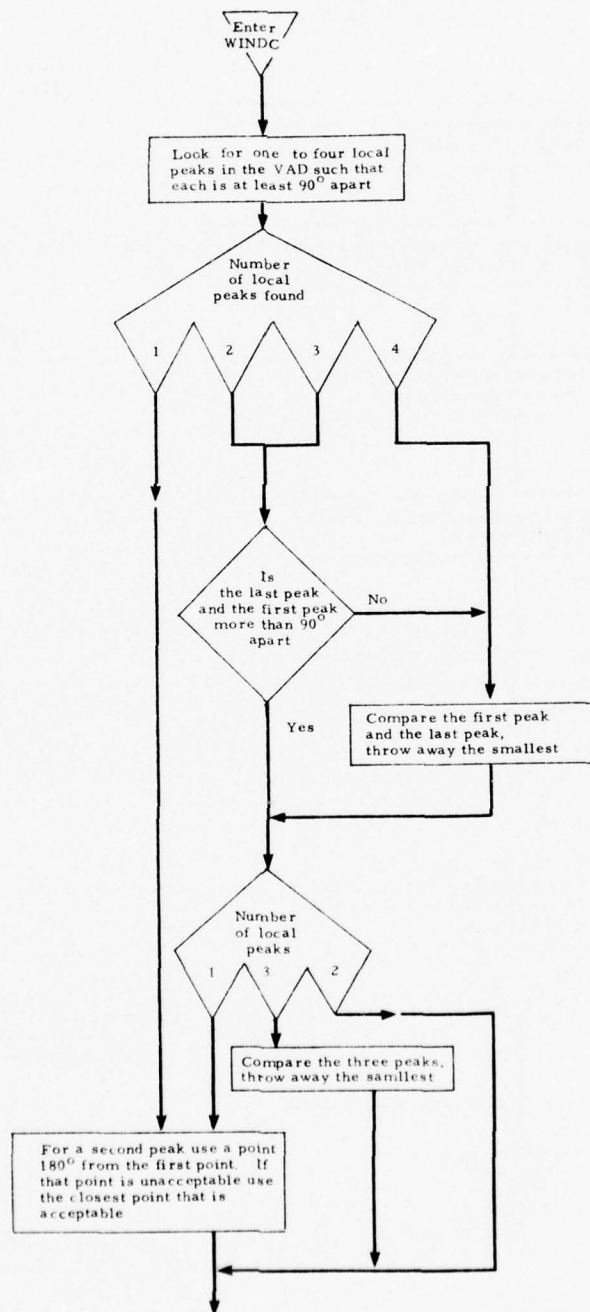

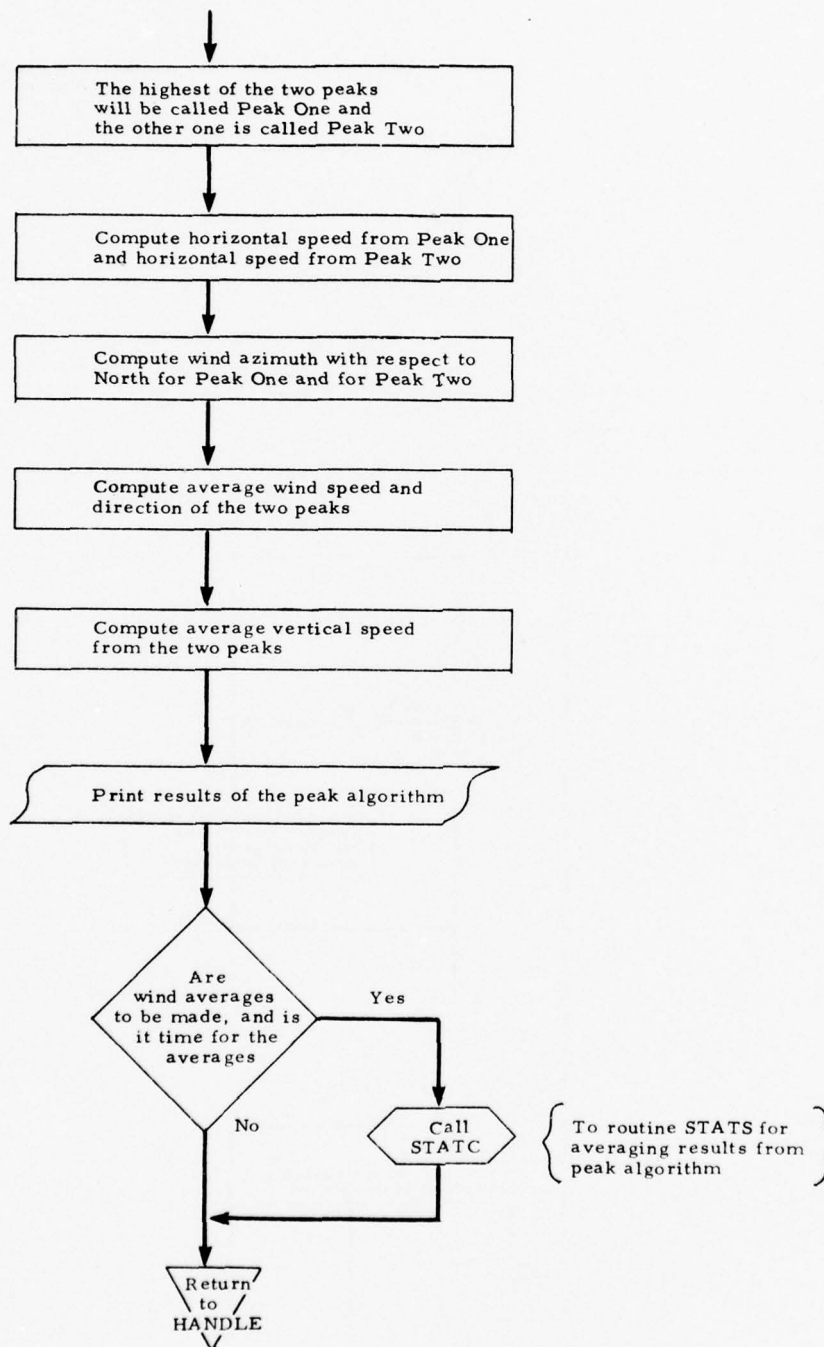

# ROUTINE WINDC

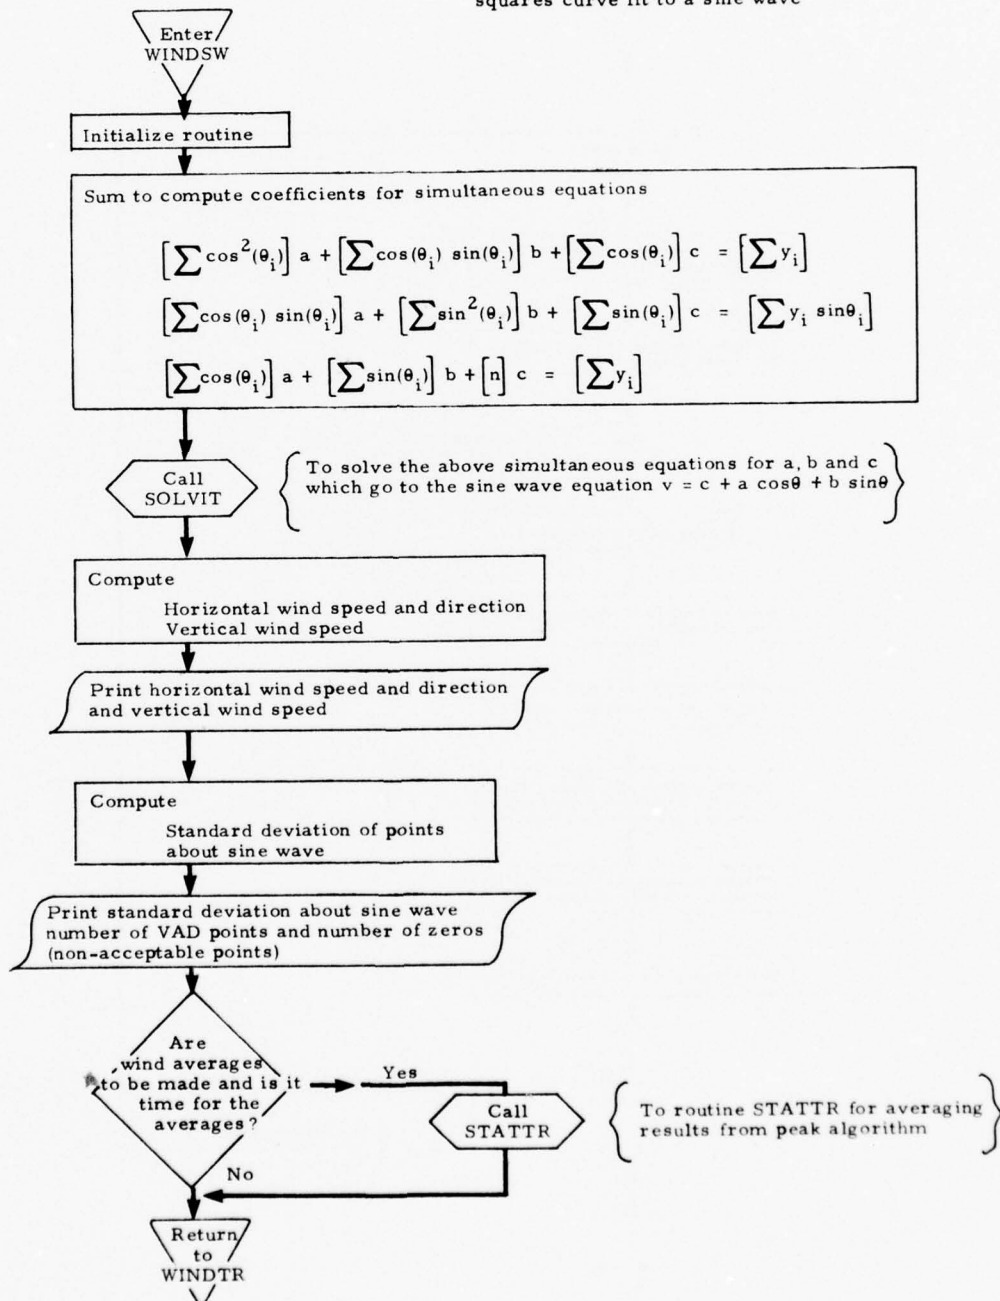

Computes wind from VAD  
using peak algorithm

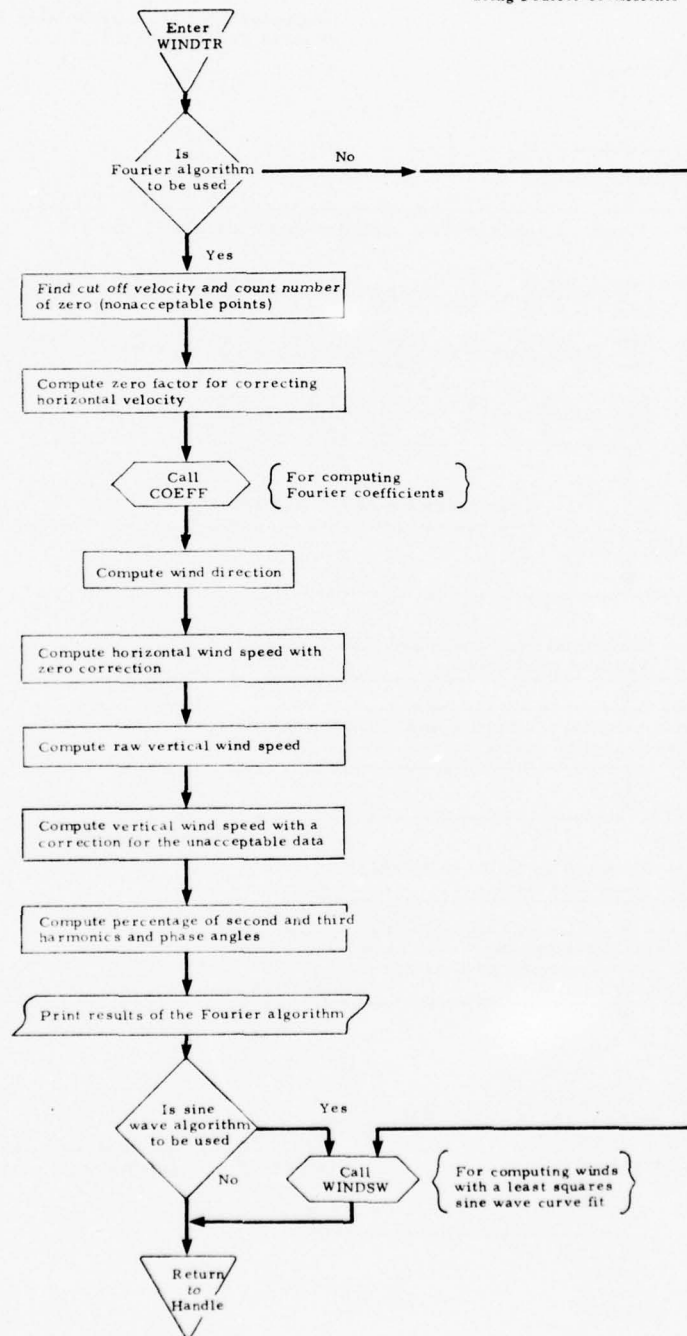

# ROUTINE WINDSW

Computes wind from VAD using a least squares curve fit to a sine wave

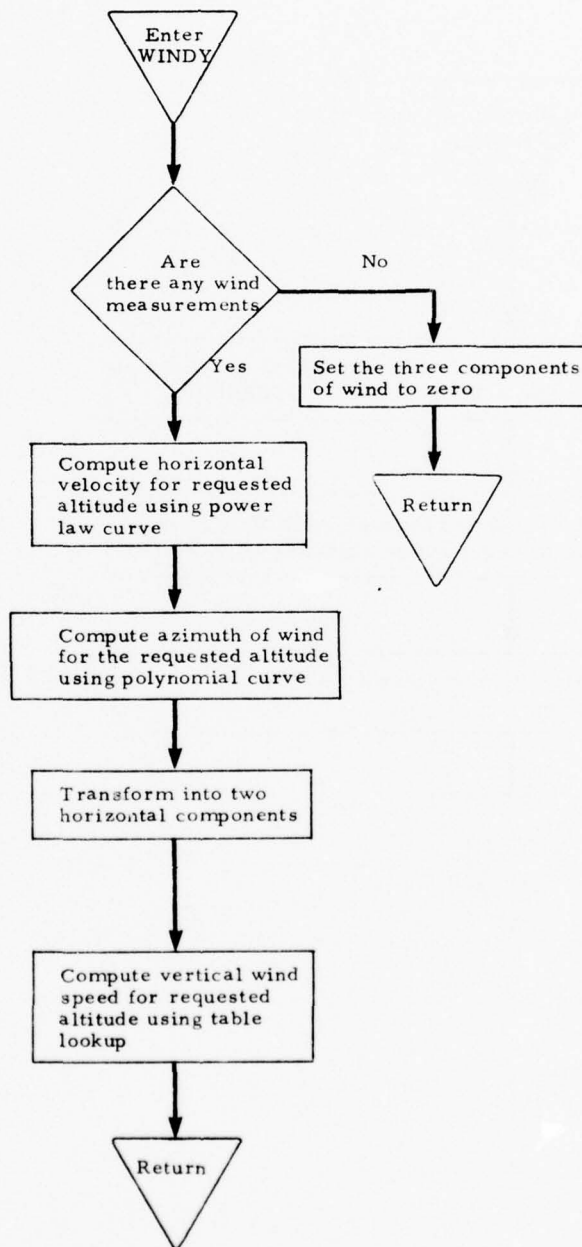

# ROUTINE WINDTR

Computes wind from VAD  
using Fourier coefficients

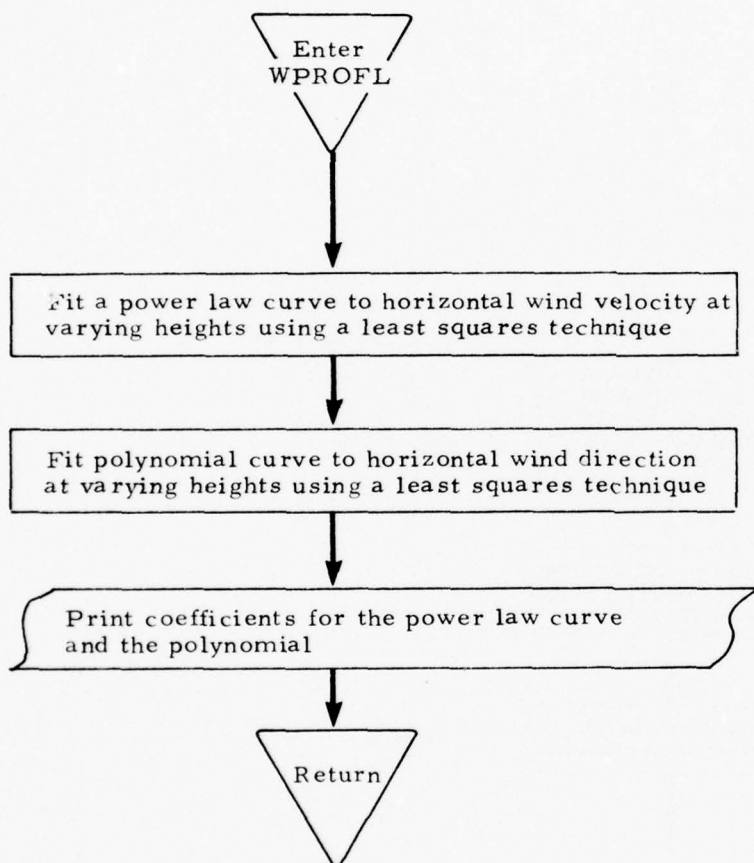

ROUTINE WINDY

Finds wind velocity at a particular altitude

ROUTINE WPROFL

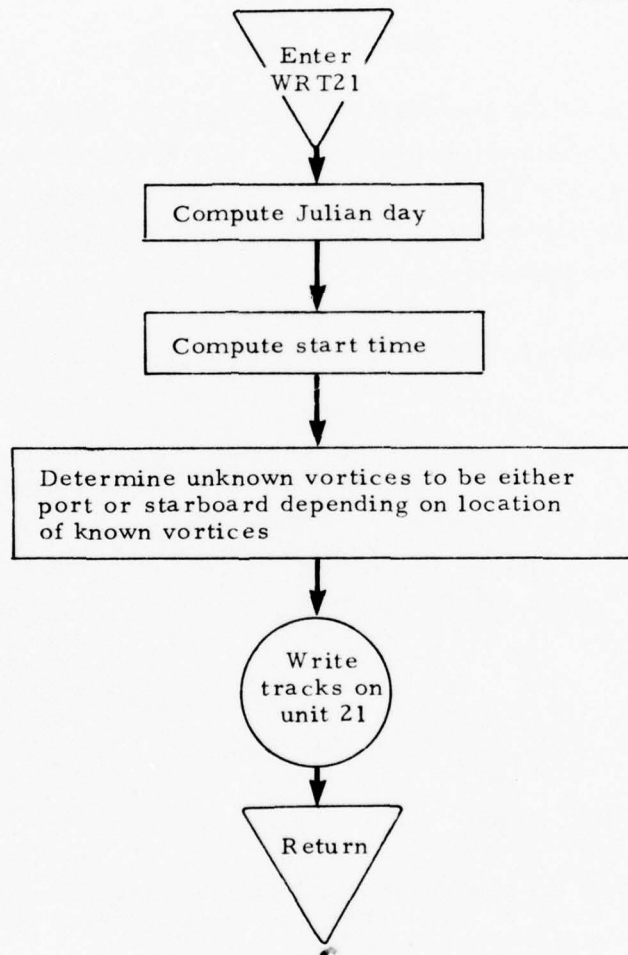

Computes wind profile  
as a function of height

ROUTINE WRT21

Writes vortex tracks  
on unit 21 for use by  
Data Management program

## Appendix B (Continued)

In addition to the flow charts presented on the previous pages, the following library routines are used in the VAD Vortex Track Program; FPLOT, SOLVIT and LSQPF. Rather than present detailed flow charts for these general library routines, they are described below in terms of the purpose, function and usage.

### ● Subroutine FPLOT

#### Purpose

FPLOT collects and stores data as they become available, and upon signal, produces a printer plot in practically any orientation and size. FPLOT should be regarded as a general purpose output routine for displaying output data in graphical form.

#### Usage

CALL FPLOT(M1, IPNT, AR, LR, ISTOP, NCU, NCMAX, V1, V2)

#### Description of Parameters

M1	is the size of the main storage array, and it should never be larger than 800, which corresponds to 400 points to be plotted.
IPNT	is a counter initialized-usually IPNT = 0 - in the calling program. It is incremented by 2 each time a new data point is entered in AR.
AR	is the main storage array. It should be in a dimension statement in the calling program. For example, DIMENSION AR(800).
LR	is an array of bytes used to hold the curve number. It should be dimensioned for M1/2. The type declaration LOGICAL*1 LR(400) should be in the calling program.

ISTOP	is the flag used to signal that all data has been entered. ISTOP=0 causes data to be stored. If ISTOP=-1 and NCU=NCMAX the program immediately branches to the plotting section. If ISTOP=1 and NCU = NCMAX a data point is stored and then the plotting section is entered.
NCU	is the curve number for which data are being entered. It must be a positive integer less than 21.
NCMAX	is the number of curves to appear on the graph. This is the largest value NCU will have.
V1	is the horizontal coordinate of the data point to be plotted.
V2	is the vertical coordinate of the data point to be plotted.
IT(1)	causes the standard horizontal size of 120 positions to be used. A positive integer will cause the horizontal size to be modified. Maximum horizontal size is 120 positions.
IT(2)	A zero causes the standard vertical size of 58 positions to be used. A positive integer will cause the vertical size to be modified. Maximum vertical size is 238 positions.
IT(3)	A zero causes the standard horizontal positive direction – to the right – to be used. A 1 causes reversal.
IT(4)	A zero causes the standard vertical positive direction – up – to be used. A 1 causes reversal.
LC(1 to 20)	Any symbols placed here will be used as plotting characters.

#### Remarks

As many as 20 different curves may appear on a single graph.  
 A maximum of 400 points can be plotted on one graph.  
 The number of points in each curve is arbitrary, but the total number of points must not be exceeded.  
 The order in which the points of different curves is computed is arbitrary.  
 The graph size is adjustable up to 120 x 238 positions.  
 The standard size is 120 x 58 positions – one page.  
 The standard horizontal and vertical positive directions can be independently changed.

Scaling of data is automatic, the best even scale factor being selected to maximize graph resolution within the available space.

A border of XXXXXXXX is automatically supplied.

The background grid is arranged so that one of the major divisions will pass through zero. The background grid is marked only at the intersections of the major divisions

If the coordinate of zero appears on a graph, a solid line appears so that this major division stands out.

Numerical values are supplied for all major divisions.

The program plots vertically or horizontally with equal ease.

When collecting data for several curves to appear on a single graph, no plots are made until the signal is given and the last data point for the last curve has been stored.

Should one inadvertently try to store more data than storage has been set aside, data storage is bypassed. Only the data stored are used in making the graph.

A curve with one point, or a curve of a constant can be plotted.

Stored data are undisturbed and available for later use.

#### ● Subroutine SOLVIT

##### Purpose

Compute a highly accurate solution to the matrix equation  $AX = B$  where  $A$  is an  $N \times N$  matrix, and  $X$  and  $B$  are vectors.

##### Usage

CALL SOLVIT (A, N, M, B, X, ACC, MAXIT, IT, IN, W)

##### Description of Parameters

A	$N \times N$ matrix of coefficients
N	number of rows of A
M	number of rows of array in which A is stored
B	right-hand side of equation $AX = B$
X	solution vector

ACC	accuracy desired
MAXIT	maximum number of iterations to be tried. (10 should be sufficient.) If MAXIT = 0, no iterations will be performed.
IT	internal indicator set by program to: = -1 if matrix is singular = 0 if convergence failed within MAXIT iterations = k the number of iterations it took to converge
IN	to be set = 1 for first entry to the subroutine = 2 for subsequent entries if A has not been changed.
W	N x (N + 5) array used as working storage.

#### Method

The Gaussian elimination method with partial pivoting is used to decompose the matrix to upper and lower triangular matrices. (These triangular matrices are saved.) From the residual vector  $B - AX$ , a correction vector is computed and added to  $X$ . The process is repeated until the residual vector is within the tolerance.

The initial scaling of each row, to bring the maximum element between  $1/2$  and 1, is done using factors equal to integral powers of 2 to eliminate round off errors which otherwise might have been introduced.

The method is due to Cleve Moler, JPL, presented at SHARE XXV, Chicago.

#### Storage Requirements

116 locations.

#### Restrictions

In most cases, eight digits accuracy can be attained.

W must not be used between calls to SOLVIT when solving for multiple right-hand sides. Matrix A is destroyed.

#### Note

SOLVIT is only a driver for the deck SIME (entry points SIMEQA and SIMEQB): thus two decks comprise this subroutine. In addition, this subroutine uses the library subroutine LOG2.

#### ● Subroutine LSQPF, LSQPF1

#### Purpose

This program will fit polynomials of order one through seven to  $n$  given points  $(X_1, Y)$ ,  $(X_2, Y_2)$ , ---  $(X_n, Y_n)$  by the method of least squares. The order and spacing of the points is immaterial and the points need not all be distinct.

#### Usage

- a. CALL LSQPF (X, Y, K, N, M, C, IERR) or
- b. CALL LSQPF1 (X, Y, K, N, M, C, IERR)

#### Description of Parameters

X	for both entries X is the first location of the block of $X_i$ values (real array)
Y	for both entries Y is the first location of the block of $Y_i$ values (real array)
K	for both entries K is zero if residuals are not needed; is nonzero if residuals are wanted (integer)
N	for both entries N is the number of points to be fitted (integer)
M	for entry (a), M is the highest order polynomial desired. The routine will compute polynomial fits of degree one through M and return all coefficients. For entry (b), the routine computes a polynomial fit of degree M only. $2 \leq M \leq 7$ (integer)

C

for both entries, C is the first location of the block where the coefficients, standard deviation, and residuals will be stored.

for entry (a), the dimension of C must be  $M(M+5)/2$  if  $K = 0$ , and  $M(M+5)/2 + N * M$  if  $K \neq 0$ . The coefficients,  $a_i$ , the standard deviation,  $\sigma$ , and the residuals,  $R_j$ , are stored in the following order beginning at location C:

$A_0^{(1)}, A_1^{(1)}, \sigma^{(1)}, A_0^{(2)}, A_1^{(2)}, A_2^{(2)}, \sigma^{(2)}, \dots, A_0^{(M)},$   
 $A_1^{(M)}, \dots, A_m^{(M)}, \sigma^{(M)}, R_1^{(1)}, R_2^{(2)}, R_2^{(2)}, \dots, R_n^{(2)}, \dots$   
 $R_1^{(M)}, R_2^{(M)}, \dots, R_n^{(M)}.$

The location of  $A_0$  of polynomial degree  $P (1 \leq P \leq M)$  is  $C(I)$  where  $I = P(P+5)/2 - (P+1)$ . The location of  $R_1$  of polynomial degree  $P (1 \leq P \leq M)$  is  $C(I)$  where  $I = M(M+5)/2 + N(P-1)+1$ .

For entry (b), the dimension of C must be  $(M+2)$  if  $K = 0$ , and  $(M+2+N)$  if  $K \neq 0$ . The coefficients are stored in  $C(1)$  through  $C(M+1)$ , the standard deviation in  $C(M+2)$ , and the residuals in  $C(M+3)$  through  $C(M+2+N)$ . (real array)

IERR

for both entries, IERR is the error flag; it will contain 0 if no error occurred, and some number if an error has occurred. There are two reasons for an error: one of the pivotal elements is zero, or an overflow has occurred. (integer)

### Method

The method of solution is as follows:

Given a set of  $n$  points,  $(X_i, Y_i)$ , we require sets of coefficients,  $a_j$ , such that

$$\sum_{j=0}^P a_j (X_i)^j$$

is the best least squares fit to  $Y_i$  over all  $i$ . This is done by first normalizing the  $X_i$  to the interval  $(-1, +1)$  by use of the formula

$$X'_i = \frac{X_i}{\max(|X_0|, \dots, |X_n|)}$$

We can then work in terms of Chebychev polynomials,  $T_k$ , where

$$T_0 = 1$$

$$T_1 = X'_1$$

$$T_k = 2 X'_1 T_{k-1} - T_{k-2}$$

for  $k = 2(1)p$ . We now seek  $t_j$  such that

$$\sum_{j=0}^p t_j T_j(X'_1)$$

gives the best least squares fit. The residuals,  $R_i^k$ , are

$$R_i^{(k)} = \sum_{j=0}^k [a_j (X'_1)^j] - Y_i, \quad k = 1(1)p$$

The unbiased estimate of the standard deviation of the  $k^{\text{th}}$  order polynomial fit is

$$\sigma^{(k)} = \frac{\sum_{i=1}^n |R_i^{(k)}|}{n} \sqrt{\pi/2}$$

### Restrictions

The value of  $M$  must be in the range 2 through 7. Care should be exercised in using this routine since considerable loss in accuracy of the coefficients is sometimes involved.

A diagram showing a runway and a landing aircraft. The runway is represented by two parallel lines extending from the bottom left towards the top right. A north arrow labeled 'N' is at the top left, pointing upwards. An arc between the north arrow and the runway is labeled 'Runway Azimuth'. At the bottom left, a landing aircraft is shown. A coordinate system is centered at the aircraft with three axes: a vertical axis labeled '+z', a horizontal axis pointing right labeled '+x', and a diagonal axis pointing up and to the right labeled '+y'.

Appendix D  
REPORT OF INVENTIONS

Under this contract the Lockheed LDV system was modified, calibrated and tested in an airport environment. A base of wind and wake vortex measurements were obtained. The contract objectives were met and no innovation, discovery nor invention was made.
